CHEM–04	Bounding single container release of toxic gas (selenium hexafluoride) from waste cylinder storage.	Approximately 0.004 per year (i.e., one in about 250 years)	Average number of off-site persons exposed above ERPG–2 level is zero; toxic effects generally limited to the source's TA (TA–54).	0 No changes in frequency or severity from the No Action Alternative.
CHEM–05	Bounding multiple cylinder release of toxic gas (sulfur dioxide) from waste cylinder storage.	Approximately 0.00051 per year (i.e., one event in approximately 2,000 years)	Under conservative daytime conditions, no one outside the source area (TA–54) would see levels above ERPG–2. Under least favorable conditions, 13 persons could be exposed above ERPG–3 levels.	0 No changes in frequency or severity from the No Action Alternative.

[a] Accident likelihood estimates are conservative, given the information available.
[b] Conservative assumptions have been employed in estimating the quantity and form of the hazardous materials available for release.
[c] Accident consequences are generally conservative (pessimistic), but utilize average (rather than most unfavorable) weather conditions.

5.4 IMPACTS OF THE REDUCED OPERATIONS ALTERNATIVE

5.4.1 Land Resources

5.4.1.1 *Land Use*

Changes to land use and land use categories under the Reduced Operations Alternative would be the same as for the No Action Alternative.

5.4.1.2 *Visual Resources*

Changes to visual resources under the Reduced Operations Alternative would be the same as for the No Action Alternative.

5.4.1.3 *Noise*

Changes to noise levels, air blasts and ground vibrations associated with high explosives testing under the Reduced Operations Alternative would be the same as for the No Action Alternative. The total of LANL activities would decrease with a corresponding slight decrease in total noise producing events, which would reduce the potential to impact workers.

5.4.2 Geology and Soils

Potential impacts for the Reduced Operations Alternative on geology and soils would be the same as those for the No Action Alternative.

5.4.3 Water Resources

5.4.3.1 *Surface Water*

Table 5.4.3.1–1 shows the total flow from the NPDES outfalls for each of the major watersheds under the Reduced Operations Alternative. In volume III, appendix A, Table A.1–1 presents a more detailed table of the NPDES outfalls for all four alternatives by facility (key and non-key), watershed, and location. The estimated total gallons discharged into all watersheds equals 218 million gallons (825 million liters) under the Reduced Operations Alternative. This is a decrease from the index effluent volume of 233 million gallons (882 million liters).

NPDES outfall effluent quality during the period of the SWEIS (1997 through 2006) is expected to be the same under this alternative as described for the No Action Alternative, including the radionuclide concentrations in effluent from TA–50, as presented in Table 5.2.3.2–2. The only canyon that has an increase in outfall flow over the baseline is Sandia Canyon. The projected increase in flow to Sandia Canyon is slightly more than one-half that projected for the No Action Alternative. The potential impacts resulting from this increase in flow in Sandia Canyon should be the same as discussed under the No Action Alternative. For the Reduced Operations Alternative, there are no new activities that would result in changes in stormwater runoff.

5.4.3.2 *Alluvial Groundwater*

The relative decreases in NPDES outfall discharges (as compared to No Action) are expected to result in proportionally lower alluvial groundwater volumes.

The projected discharge from RLWTF into Mortandad Canyon under the Reduced Operations Alternative is 5.3 million gallons (20 million liters) per year, about the same as the RLWTF index volume of 5.5 million gallons (21 million liters) per year.

The new HELWTF will likely result in improved water quality to Canyon de Valle, as discussed in the No Action Alternative.

TABLE 5.4.3.1–1.—*NPDES Discharges by Watershed Under the Reduced Operations Alternative*[a]

WATERSHED	# OUTFALLS		FLOWS (MGY)					
			KEY FACILITIES		NON-KEY		TOTALS	
	INDEX	REDUCED	INDEX	REDUCED	INDEX	REDUCED	INDEX	REDUCED
Ancho	2	0	0.1	0.0	0.0	0.0	0.1	0.0
Cañada del Buey	3	3	0.0	0.0	6.4	6.4	6.4	6.4
Chaquehui	1	0	0.0	0.0	5.8	0.0	5.8	0.0
Guaje	7	7	0.0	0.0	0.7	0.7	0.7	0.7
Los Alamos	12	8	19.2	16.4	0.5	0.2	19.7	16.6
Mortandad	12	7	42.0	28.3	10.9	5.1	52.9	33.4
Pajarito	17	11	8.4	1.8	0.8	0.8	9.2	2.6
Pueblo	1	1	0.0	0.0	1.0	1.0	1.0	1.0
Sandia	11	8	4.4	15.4	103.5	127.9	107.9	143.3
Water	21	10	29.5	14.1	0.0	0.0	29.5	14.1
Totals	87	55	103.6	76.0	129.6	142.0	233.2	218.1

MGY = millions of gallons per year

[a] NPDES Information Sources: Index information was provided by the Surface Water Data Team Reports of August 1996 (Bradford 1996) and as modified in 1997 (Garvey 1997). Outfall flow projections for the alternatives were based on the outfalls remaining as of November 1997. Additional outfalls may be eliminated in the future (as discussed in the *Environmental Assessment for Effluent Reduction* [DOE 1996e]) as well as several other outfalls that may be closed as part of LANL's ongoing outfall reduction program.

5.4.3.3 *Perched Groundwater*

Groundwater flow and contaminant pathways to the intermediate perched groundwater bodies are not well characterized nor understood. It is possible that NPDES discharges to Los Alamos and Sandia Canyons under the Reduced Operations Alternative, could contribute to recharge of the intermediate perched groundwater and contaminant transport beneath Los Alamos and Sandia Canyons. However, unlike the No Action and the other alternatives, NPDES discharges to Los Alamos Canyon under the Reduced Operations Alternative will be slightly less than the index.

5.4.3.4 *Main Aquifer*

Recharge mechanisms to the main aquifer are uncertain. However, for the same reasons as discussed under the No Action Alternative, impacts resulting from decreased NPDES outfall flows under the Reduced Alternative should be negligible. A conservative projection of LANL water use under the Reduced Operations Alternative is 602 million gallons (2,279 million liters) per year. Los Alamos County and the NPS did not provide projections, but in 1994 the County used about 958 million gallons (3,626 million liters) from this water right and the NPS used about 5 million gallons (19 million liters). Based on this information, it is expected that the water requirements of this community can be met within the existing water rights from the main aquifer.

For the purposes of modeling drawdown of the main aquifer, annual water use projections were made. The total water usage from DOE water rights was projected to average 1,451 million gallons (5,492 million liters) per year under the Reduced Operations Alternative, with a maximum annual use of 1,470 million gallons

(5,564 million liters) and a minimum annual use of 1,444 million gallons (5,466 million liters).

The model results reflect water level changes at the top of the main aquifer across the alternatives, given continued draw from the aquifer by DOE, Española, and Santa Fe. Table 5.4.3.4–1 shows predicted water level changes at the surface of the main aquifer during the period from 1997 through 2006 for the Reduced Operations Alternative; as noted in section 5.2.3.1, these changes are not all due to LANL operations. Although the water use modeled includes water use in Española and Santa Fe, the differences between the alternatives are due only to LANL operations. The impacts to the volume of water in the main aquifer under this alternative are very similar to those described for the No Action Alternative; the drawdowns in the DOE well fields are minimal relative to the total thickness of the main aquifer, and the volume of water to be used over the period from 1997 through 2006 is negligible relative to the volume of water in storage. Details of the conceptual model, assumptions, uncertainties and limitations, and input parameters for the groundwater model are described in volume III, appendix A.

TABLE 5.4.3.4–1.—*Maximum Water Level Changes at the Top of the Main Aquifer Under the Reduced Operations Alternative (1997 Through 2006)*

WATER LEVEL CHANGE IN FEET[a,b]	
AREA OF CONCERN ON SITE	
Pajarito Well Field	-10.7
Otowi Well Field (Well 0-4)	-10.3
AREA OF CONCERN OFF SITE	
DOE - Guaje Well Field	-8.1
Santa Fe Water Supply	
Buckman Well Field	+21.7
Santa Fe Well Field	-20.6
San Juan Chama Diversion	0.0
Springs	
White Rock Canyon Springs, Maximum Drop	0.0
White Rock Canyon Springs, Maximum Rise	+1.0
Other Springs (Sacred, Indian)	+3.8
San Ildefonso Pueblo Supply Wells	
West of Rio Grande	
Household, Community Wells	+0.6
Los Alamos Well Field	+3.8
East of Rio Grande	
Household, Community Wells	0.0

[a] Negative value (-) indicates water level drop; positive value (+) indicates water level rise.
[b] Also, the water level changes projected by the regional MODFLOW model represent average changes over a whole grid- cell (i.e., a square that is a mile on a side). They are, for the most part, not predictive of the water level changes at any single point within the cell (for example, a supply well). Pumping wells have characteristic "cones of depression" where the water surface reflects an inverted cone, and water levels at the well may be quite different from levels even a few ten's of feet away. Whether any individual well would exhibit water level changes consistent with the predicted grid-cell average change is a function of, for example, its location within the grid-cell; proximity to other pumped wells; and the individual well operation, construction, and hydraulics. Hence, the water level changes predicted by the model can only be considered qualitatively and can not be considered as finite changes.

5.4.4 Air Quality

5.4.4.1 *Nonradiological Air Quality Impacts*

Criteria Pollutants

Criteria pollutant emissions under the Reduced Operations Alternative are less than those under the Expanded Operations Alternative. Because the bounding analysis of criteria pollutant emissions for all alternatives (based on the emissions under the Expanded Operations Alternative) results in estimated concentrations of each pollutant below the standards established to protect human health with an ample margin of safety, criteria pollutant emissions under the Reduced Operations Alternative would also be below these levels.

Toxic Air Pollutants

As discussed in section 5.1.4, the only toxic air emissions with the potential to impact human health and the environment under any alternatives are those associated with high explosives test site operations and the additive emissions from all the pollutants from all TAs on receptor sites located near the Los Alamos Medical Center. Under the Reduced Operations Alternative, such emissions are projected to be similar to those addressed in the No Action Alternative (section 5.1.4). Therefore, pollutants released from LANL operations under the Reduced Operations Alternative are not expected to cause air quality impacts that would affect human health and the environment.

5.4.4.2 *Radiological Air Quality Impacts*

This section addresses the radiation dose to the FS MEI, LANL MEI and the population dose from LANL radionuclide air emissions under the Reduced Operations Alternative.

Facility-Specific Maximally Exposed Individual

Table 5.4.4.2–1 shows the FS MEI doses under the Reduced Operations Alternative. The highest MEI dose was 1.88 millirem per year, which is 18.8 percent of the regulatory limit for the air pathway. This table shows the EPA regulatory limit would not be exceeded from emissions of these facilities under the Reduced Operations Alternative.

LANL Maximally Exposed Individual

The location of the highest dose from all facility emissions was 2,625 feet (approximately 800 meters) north-northeast of TA–53. LANL MEI dose was calculated to be 1.88 mrem per year under the Reduced Operations Alternative.

TABLE 5.4.4.2–1.—*Facility-Specific Information Reduced Operations Alternative*

KEY FACILITY	DOSE[a] (mrem/yr)
TA–3-29 (CMR)	0.36
TA–3-66 (Sigma)	0.36
TA–3-102 (Shops)	0.29
TA–11 (HE Testing)	0.31
TA–15/36 (Firing Sites)[c]	1.76
TA–16 (Tritium Facility)	0.22
TA–18 (Pajarito Site)	1.51
TA–21 (Tritium Facility)	1.22
TA–48 (Radiochemistry Laboratory)	1.08
TA–55 (Plutonium Facility)	1.08
TA–53 (LANSCE)[b]	1.88
TA–54 (Boundary)[c]	0.68
TA–54 (White Rock)	0.39

[a] For each FS MEI, the total dose was calculated by adding the contributions from each modeled facility. An MEI does not leave or take protective measures.
[b] This is also the LANL MEI. Five specific sources were modeled from TA–53. These include the TA–53 ES–2, ES–3, IPF, LEDA, and combined diffuse emissions.
[c] Two FS MEI locations were considered for TA–54 because Area G is bordering San Ildefonso Pueblo land. The first is a MEI location at the LANL boundary, 1,197 feet (365 meters) northeast of Area G. No person from the Pueblo currently is known to live along this boundary. The second is an actual MEI location in the town of White Rock, approximately 5,331 feet (1,625 meters) southeast of Area G.

Population Dose

The collective dose to the population living within a 50-mile (80-kilometer) radius from LANL was calculated to be 10.83 person-rem per year under the Reduced Operations Alternative. TA–15/36 accounted for 65.3 percent of this dose (collective diffuse emissions, including those from these TAs, accounted for 66.3 percent of this dose).

The values reported for population doses for this alternative, as well as the other alternatives, is higher than has been reported in the recent annual environmental reports. It is important to recognize that the alternatives analyzed represent increased operations when compared to recent history. The material throughput at the different facilities under the various alternatives is presented in chapter 3, section 3.6.

Isodose Maps

The isodose maps for the 50-mile (80-kilometer) region are shown on Figures 5.4.4.2–1 and 5.4.4.2–2.

5.4.5 Ecological Resources, Biodiversity, and Ecological Risk

Impacts to ecological resources and biodiversity resulting from reducing the scale of operations would not vary appreciably from those of the No Action Alternative. An overall reduction in outfall discharges could cause a commensurate decrease in the extent of affected wetlands. There would not be any incremental changes from the No Action level of ecological risk.

5.4.6 Human Health

The consequences of implementing the Reduced Operations Alternative on public health and worker health are presented below. As discussed in section 5.1.6, "risk," as used in the SWEIS human health analysis, refers to the probability of toxic or cancer mortality consequences under the specific exposure scenarios analyzed.

5.4.6.1 *Public Health*

The consequences of continued operations of LANL on public health under the Reduced Operations Alternative are presented below for the same topics discussed in section 5.2.6.1.

Regional Consequences of Airborne Radioactivity Inhalation and Immersion

The LANL MEI was estimated to be 2,625 feet (800 meters) north-northeast of LANSCE (TA–53). This location is within the LANL reservation, and the dose at this location is estimated to be 1.88 millirem per year (section 5.4.4.2), corresponding to a 72-year lifetime dose of 0.14 rem. This location borders the Los Alamos townsite and is a conservative estimate for an MEI from LANL emissions. The background (TEDE) dose in the Los Alamos area is estimated to be 360 millirem per year; thus, the dose to the MEI is 0.5 percent of the background dose.

Table 5.4.6.1–1 summarizes the LANL MEI dose and presents the corresponding risk of excess LCF to the MEI. The risk of development of nonfatal cancer is also presented. These risks are presented on a lifetime basis, assuming that the hypothetical LANL MEI received the estimated dose of 1.88 millirem each year for a 72-year life. The excess LCF risk was estimated to be 0.000068 over a lifetime.

TABLE 5.4.6.1–1.—*Estimated Public Health Consequences for LANL MEI and the Population Within a 50-Mile (80-Kilometer) Radius of LANL for the Reduced Operations Alternative*

PARAMETER	LANL MEI	50-MILE (80-KILOMETER) RADIUS POPULATION
Dose	1.88 millirem/year	10.83 person-rem/year
Excess LCF	0.000068/lifetime (72 year)	0.0054/year of operations

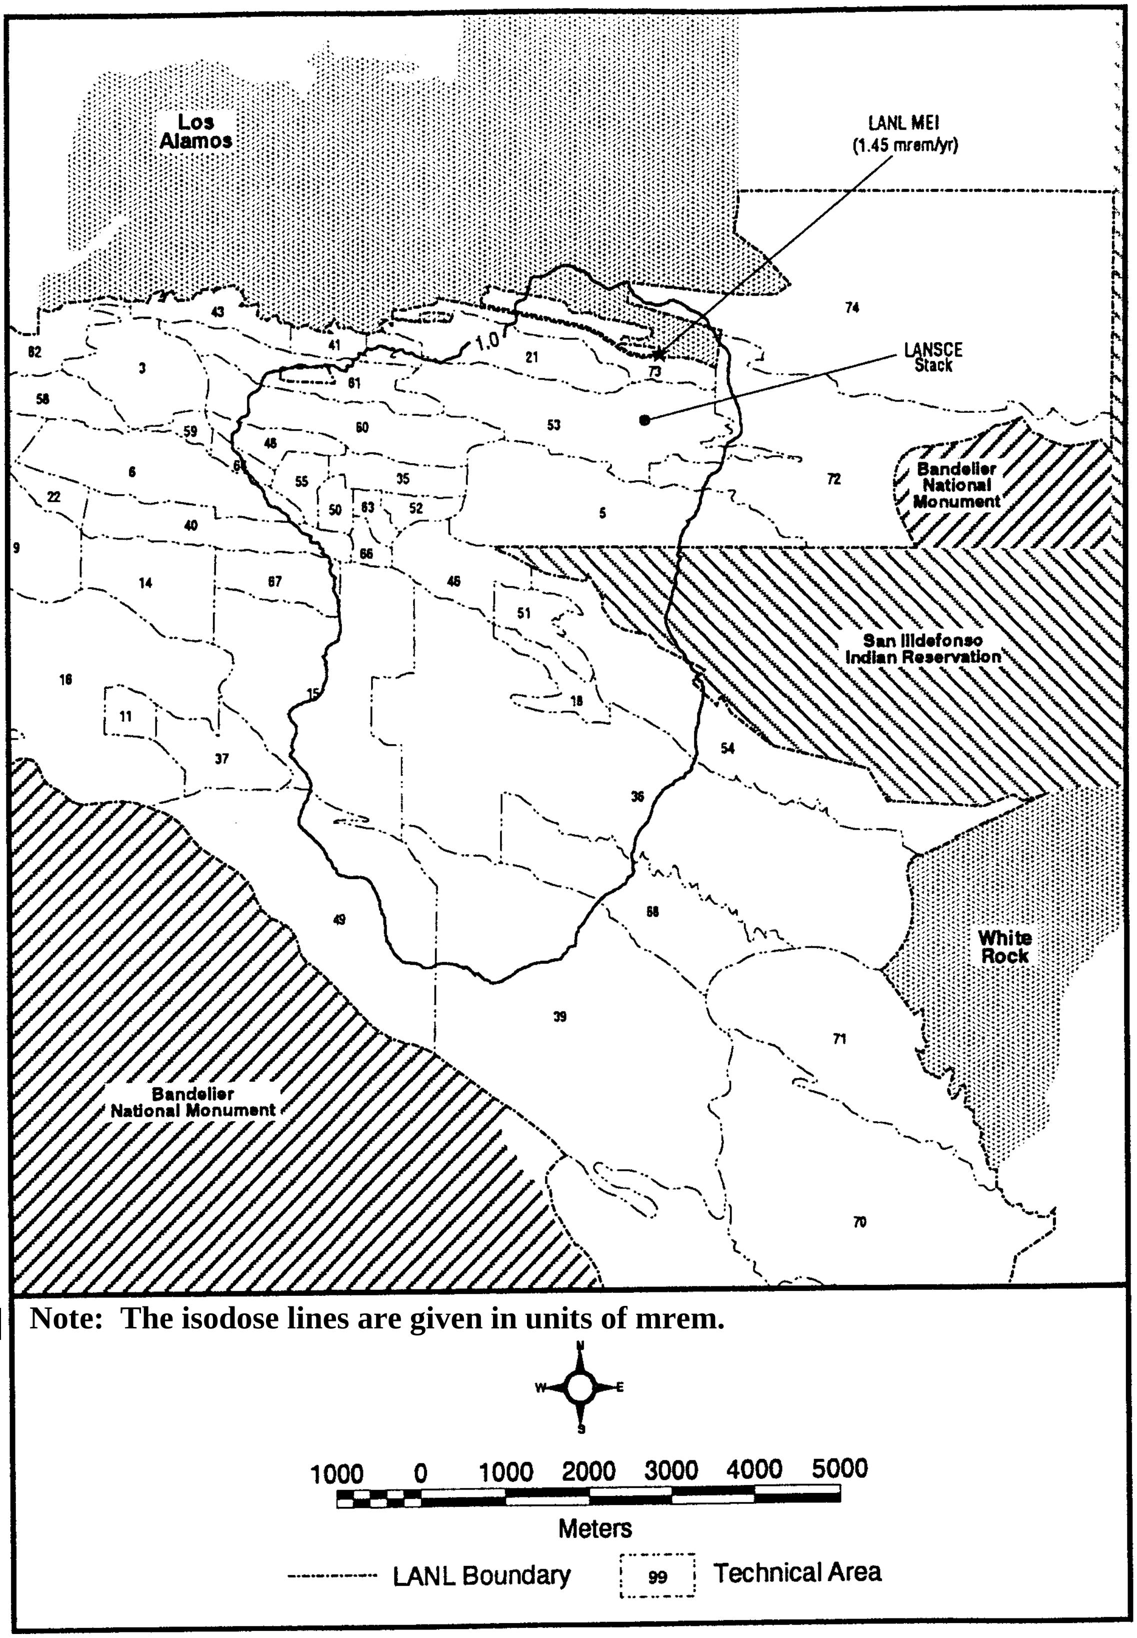

FIGURE 5.4.4.2–1.—*Isodose Map Showing Doses Greater Than 1 Millirem per Year for the Reduced Operations Alternative*.

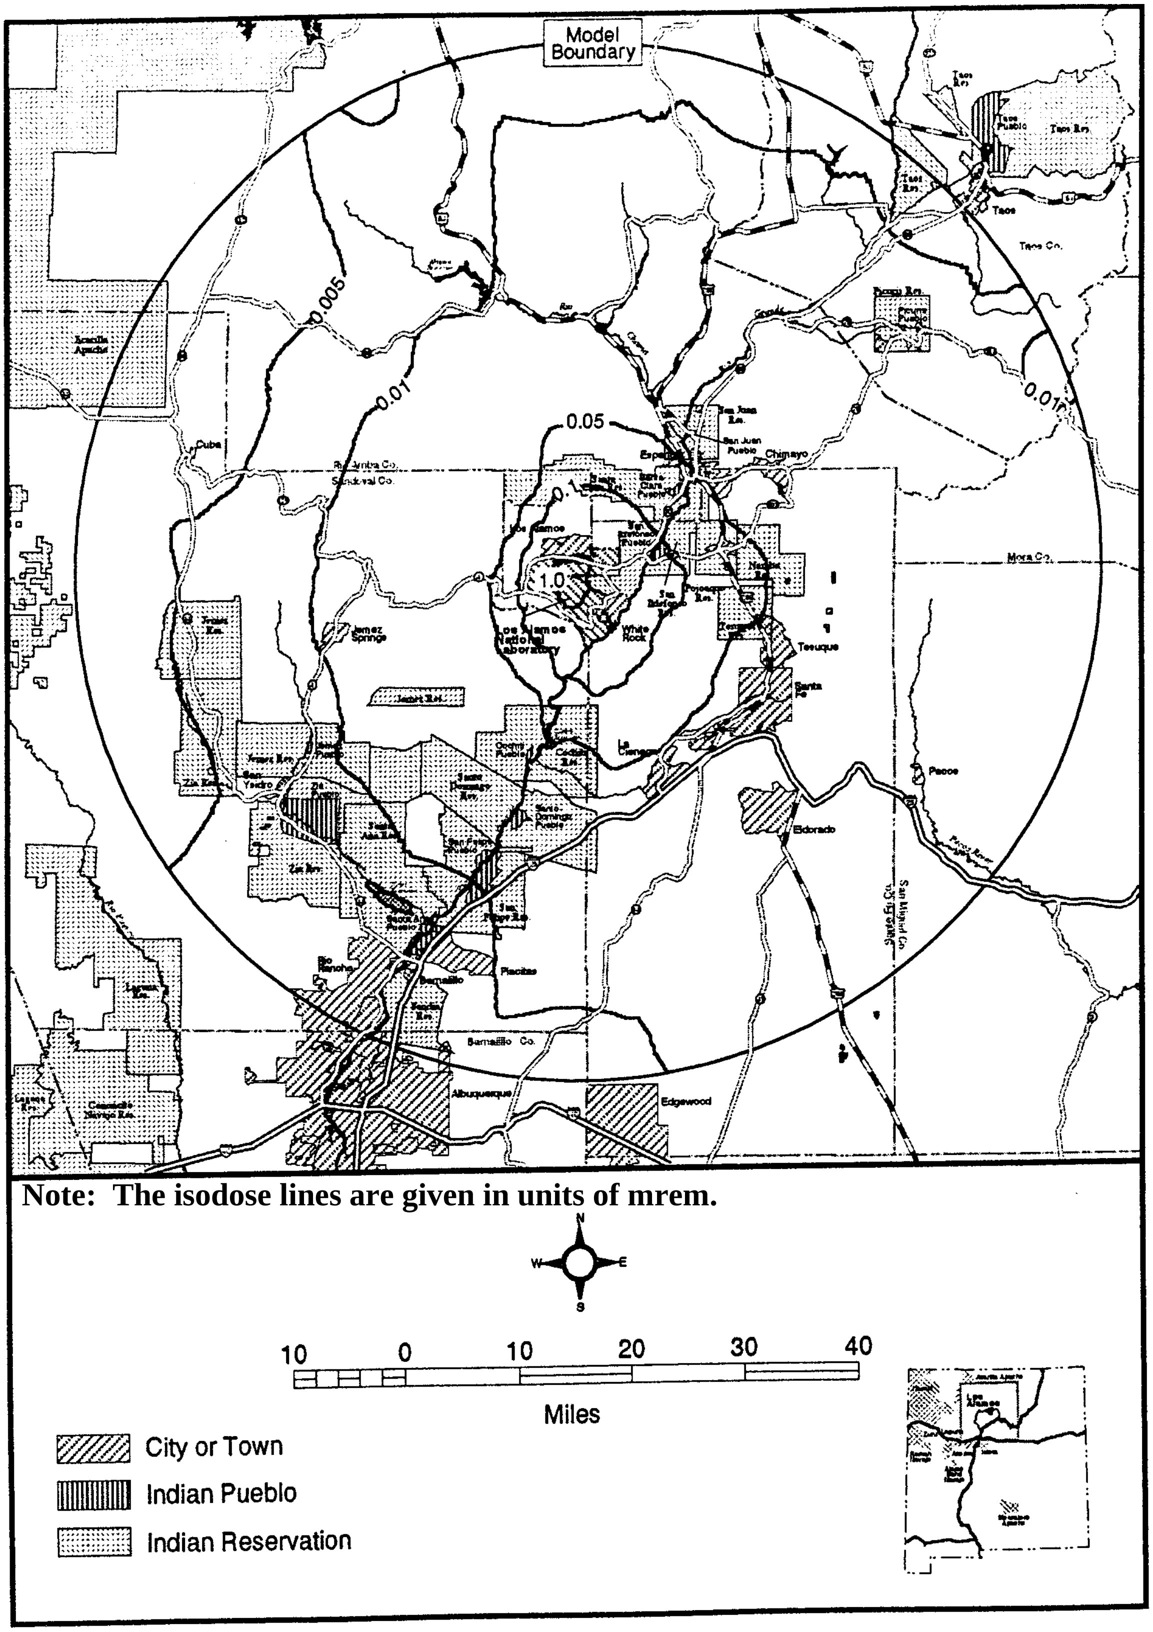

FIGURE 5.4.4.2–2.—*Isodose Map Showing Doses Less Than 1 Millirem per Year for the Reduced Operations Alternative.*

The isodose maps showing both the estimated dose near LANL and within a 50-mile (80-kilometer) radius of LANL are given in Figures 5.4.4.2–1 and 5.4.4.2–2. The population dose within the 50-mile (80-kilometer) radius is also given in Table 5.4.6.1–1, estimated to be 10.8 person-rem per year. As reflected in the table, the annual operations excess LCF risk was estimated to be 0.0054.

In the Reduced Operations Alternative, there are six facilities with FS MEIs receiving a dose that would exceed 1 millirem per year (volume III, appendix B):

- LANSCE, 1.88 millirem per year to the facility MEI
- HE Testing Sites (TA–15 and TA–36), 1.76 millirem
- Pajarito Site (TA–18), 1.51 millirem
- TSTA and TSFF (TA–21), 1.22 millirem
- Radiochemistry Laboratory (TA–48), 1.08 millirem
- Plutonium Facility (TA–55), 1.08 millirem

External Radiation: Two Special Cases

As discussed in section 5.2.6.1, one contribution to public dose results from jogging or hiking for 96 hours on the access road north of TA–21 and is attributable to cesium-137 known to be on the ground within the TA. The MEI dose is not expected to change under the Reduced Operations Alternative from that estimated under the No Action Alternative (an EDE of 2.9 millirem per year and an excess LCF risk of about 1.4 x 10^{-6} per year).

The other contribution to public dose, as discussed in section 5.2.6.1, would result from TA–18 "road-open" operations. At the 95 percent confidence level, four exposures per year would be expected for the MEI out of the 100 operations per year at TA–18 under the Reduced Operations Alternative (the same as for the No Action Alternative). This would result in an annual projected MEI EDE dose of 19 millirem per year. The lifetime excess LCF risk for this dose is about 9.5 x 10^{-6} per year of operation.

Nonionizing Radiation

The only uncontained nonionizing radiation source in use or planned for LANL is the microwave transmitter in TA–49. The consequence of a public exposure to this source under the Reduced Operations Alternative is the same as for the No Action Alternative; as discussed in section 5.2.6.1, this consequence is negligible.

Consequences of Airborne Chemical Emissions

For the Reduced Operations Alternative, these consequences are the same as those under the No Action Alternative; the worst-case HI for lead did not exceed one in a million (10^{-6}); for depleted uranium, the worst-case HI did not exceed 1 in 100,000 (0.00010); and the excess LCF for beryllium (evaluated as a carcinogen) under the Reduced Operations Alternative was estimated to be less than 3.6 x 10^{-7} per year. These analyses are presented in detail in volume III, appendix D.

Carcinogenic Risk from Air Emissions

The screening process described in appendix B identified no individual carcinogenic chemical air emission that required analysis for public health consequences. For carcinogens, an estimate also was made of the combined lifetime incremental cancer risk due to all carcinogenic pollutants from all TAs (appendix B, attachment 6).

This combined cancer risk is less than 1 in 1 million for the Reduced Operations Alternative because projected emissions for this alternative are less than those analyzed for the Expanded Operations Alternative (which was just slightly above the screening guideline value of 1 x 10^{-6}).

It is believed that negligible increase in incremental combined cancer risk will result from the Reduced Operations Alternative.

Consequences of Ingestion to Residents, Recreational Users, and Special Pathways Receptors

The risk to the public from ingestion under the Reduced Operations Alternative does not differ from that associated with the No Action Alternative; this is because most of the risk is attributable to the existing levels of contamination in water and soils in the area. This is discussed further in section 5.2.6.1. Table 5.2.6.1–2 summarizes the ingestion radiological annual dose and excess LCF per year to the MEIs. Tables 5.2.6.1–2 and 5.2.6.1–3 summarize the total radiological annual ingestion dose and excess LCF to members of the public. Per Table 5.2.6.1–3, the total worst-case ingestion doses for the off-site resident of Los Alamos County and non-Los Alamos County resident are 0.011 and 0.017 rem per year, respectively. If this person is also a recreational user of the Los Alamos canyons, drinking canyon water and ingesting canyon sediments, the worst-case additional dose ranges up to 0.001 rem per year, according to the amount of time spent in the canyons (see footnote b in Table 5.2.6.1–3). If the individual has traditional Native American or Hispanic lifestyles, the values found in the final columns of the table should be used in place of the values in the first columns for off-site residents. Per the values in the final columns, these "special pathways receptors" can have worst-case 3.1 millirem per year additional dose. The associated excess LCF risks for the off-site residents are 8.6×10^{-6} per year of exposure and 9.1×10^{-7} per year of exposure for the individual who is also an avid recreational user. These worst-case doses are for a 95th percentile intake of the 95th percentile contamination level, referred to as the UCL. Ingestion pathway calculations included all radionuclides detected in the media. This includes natural background, weapons testing fallout, and previous releases. The actual contribution from continued operations at LANL is only a small fraction of this value. These values apply to the baseline and to all four alternatives. The data and analyses for these calculations are in volume III, appendix D, section D.3.3. Table 5.2.6.1–3 summarizes the risk associated with metals ingestion to MEIs in the LANL region.

Consequences to the Public Along Transportation Routes

Section 5.4.10 details the analysis of transportation consequences under this alternative. Public health consequences include the dose and excess LCF risk associated with routine, accident-free transportation. Table 5.4.10–2 shows the population dose and excess LCF for normal (accident-free) off-site shipments. The population dose and excess LCFs associated with exposures occurring during stops for transportation segments near LANL are provided in Table 5.4.6.1–2. Doses associated with living along route and sharing routes with these shipments are detailed in Table 5.4.10–2, and are less than those associated with stops. Risks associated with accidents during transportation also are discussed in section 5.4.10.

5.4.6.2 *Worker Health*

Worker risks associated with continued operations of LANL include radiological

TABLE 5.4.6.1–2.—*Radiation Doses and Excess LCF Risks Estimated to the Public at Stops During Transportation of Materials and Wastes from LANL*

ROUTE SEGMENT	PERSON-REM PER YEAR (AT STOPS)	EXCESS LCF RISK PER YEAR
LANL to U.S. 84/285	3.4	0.0017
U.S. 84/285	3.6	0.0018

(ionizing and nonionizing) risks, chemical exposure risks, and risk of injury during normal operations. The consequences to worker health from implementing the Reduced Operations Alternative are given below and detailed in appendix D, section D.2.2.

Radiological Consequences

Ionizing Radiation Consequences. Table 5.4.6.2–1 summarizes the projected doses and associated excess LCF risks from implementation of the Reduced Operations Alternative.

The collective worker dose under the Reduced Operations Alternative is conservatively projected to be 18 percent less than that measured in 1993 to 1995. In terms of the average non-zero dose, the Reduced Operations Alternative is expected to result in less than that experienced in recent years (0.08 rem per year for Reduced Operations compared with 0.097 rem per year, 1993 to 1995). The estimated lifetime excess LCF risk is 0.000033 per year of operation.

Nonionizing Radiation. It is expected that there will continue to be negligible effects to LANL worker health from nonionizing radiation sources including ultraviolet sources, infrared radiation from instrumentation and welding, lasers, magnetic and electromagnetic fields, and microwaves (including the large station at TA–49). (Also see appendix D, section D.2.2.2 for evaluation used to estimate nonionizing radiation from LANL operations to humans and wildlife, and for the estimated results.)

Chemical Exposure Consequences

It is anticipated that there will continue to be a few exposures annually, particularly exposures to:

- Airborne asbestos
- Lead paint particulates
- Crystalline silica
- Fuming perchloric acid, hydrofluoric acid
- Skin contact with acids or alkalis

Under the Reduced Operations Alternative, it is expected that there will be a worker population of approximately 9,300 individuals, approximately equal to the index period employment levels. For the purposes of the SWEIS, it is assumed that there is negligible additional benefit of the chemical hygiene program at LANL over the period analyzed, and that the rate of chemical exposures continues at the index period rates. Therefore, it is expected that reportable chemical exposures would not change from the index period, approximately one to three reportable chemical exposures per year.

Beryllium Processing Consequences. It is anticipated that beryllium operations in the Reduced Operations Alternative would be the same as in the No Action Alternative. It is not anticipated that consequences to workers would be measurable; that is, no sensitization to beryllium would be detected using the LANL industrial hygiene monitoring program.

TABLE 5.4.6.2–1.—*Annual Worker Doses and Associated Lifetime Excess LCF Risks Under the Reduced Operations Alternative*

LANL Collective Worker Dose (person-rem/yr)	170
Estimated Excess LCF Risk (across the worker population) per year of operation	0.07
Average Non-Zero Worker Dose (rem/yr)	0.08
Estimated Excess LCF Risk (average worker > 0 dose)	0.000033

Physical Safety Hazards

Table 5.4.6.2–2 compares the projected reportable accidents and injuries estimated for normal operations occurring under the Reduced Operations Alternative and that experienced during the index period. The Reduced Operations Alternative is expected to result in no change in reportable accidents or injuries due to increases in worker population. These accidents and injuries are considered as consequences of normal operations because of their frequency. These results assume that the aggressive Health and Safety Program underway at LANL does not achieve any additional reduction in reportable cases.

The consequences of these accidents and injuries are expected to be similar to those experienced in the past, and typically are those associated with health response and recovery from acute trauma. Therefore, the consequences include physical pain and therapy/treatment for recovery such as those associated with bone setting, shoulder dislocation reset, and subsequent physical therapy. Some injuries may also result in continuing consequences to the worker that could affect productivity or lifestyle, such as motor skill loss due to nerve damage or cardiovascular debilitation resulting from electrical shock or electrocution.

TABLE 5.4.6.2–2.—*Projected Annual Reportable Accidents and Injuries for the Reduced Operations Alternative Compared with the Index Period*

PARAMETER ESTIMATED	PARAMETER VALUE AND UNITS
Projected Worker Population	Approximately 9,300
Projected Reportable Accidents and Injuries	417/year
Change from Index (1993 to 1996)	Negligible Change

5.4.7 Environmental Justice

As indicated in sections 5.4.1 and 5.4.2, no substantive adverse impacts to land resources or geology and soils are anticipated for the continued operation of LANL under the Reduced Operations Alternative. Thus, no disproportionately high and adverse impacts to minority or low-income communities are anticipated for these impact areas. The potential impacts to surface and groundwater and ecological resources associated with the Reduced Operations Alternative would affect all communities in the area equally (see sections 5.4.3 and 5.4.5 for additional information on the potential for impacts to these resources). Thus, no disproportionately high or adverse impacts to minority or low-income communities are anticipated to be associated with these resource areas.

Figure 5.4.7–1 reflects the dose from radiological air emissions within 50 miles (80 kilometers) of LANL under the Expanded Operations Alternative. As discussed in section 5.2.7, impacts due to air emissions are equal to lower in the sectors with substantial minority and/or low-income populations than they are in sectors 1–3 and 6–16, and such impacts are not disproportionately high or adverse with respect to the minority or low-income populations (see section 5.4.4 regarding the impacts anticipated for air emissions under the Reduced Operations Alternative).

The air pathway is one example of the analysis of potential human health impacts. As presented in section 5.4.6, there is minimal potential for LANL operations to adversely affect human health for off-site residents or recreational users in the area around LANL under the Reduced Operations Alternative. Similarly, the special pathways have little potential to impact human health under this alternative. Thus, the Reduced Operations Alternative would not present disproportionately high or adverse impacts to

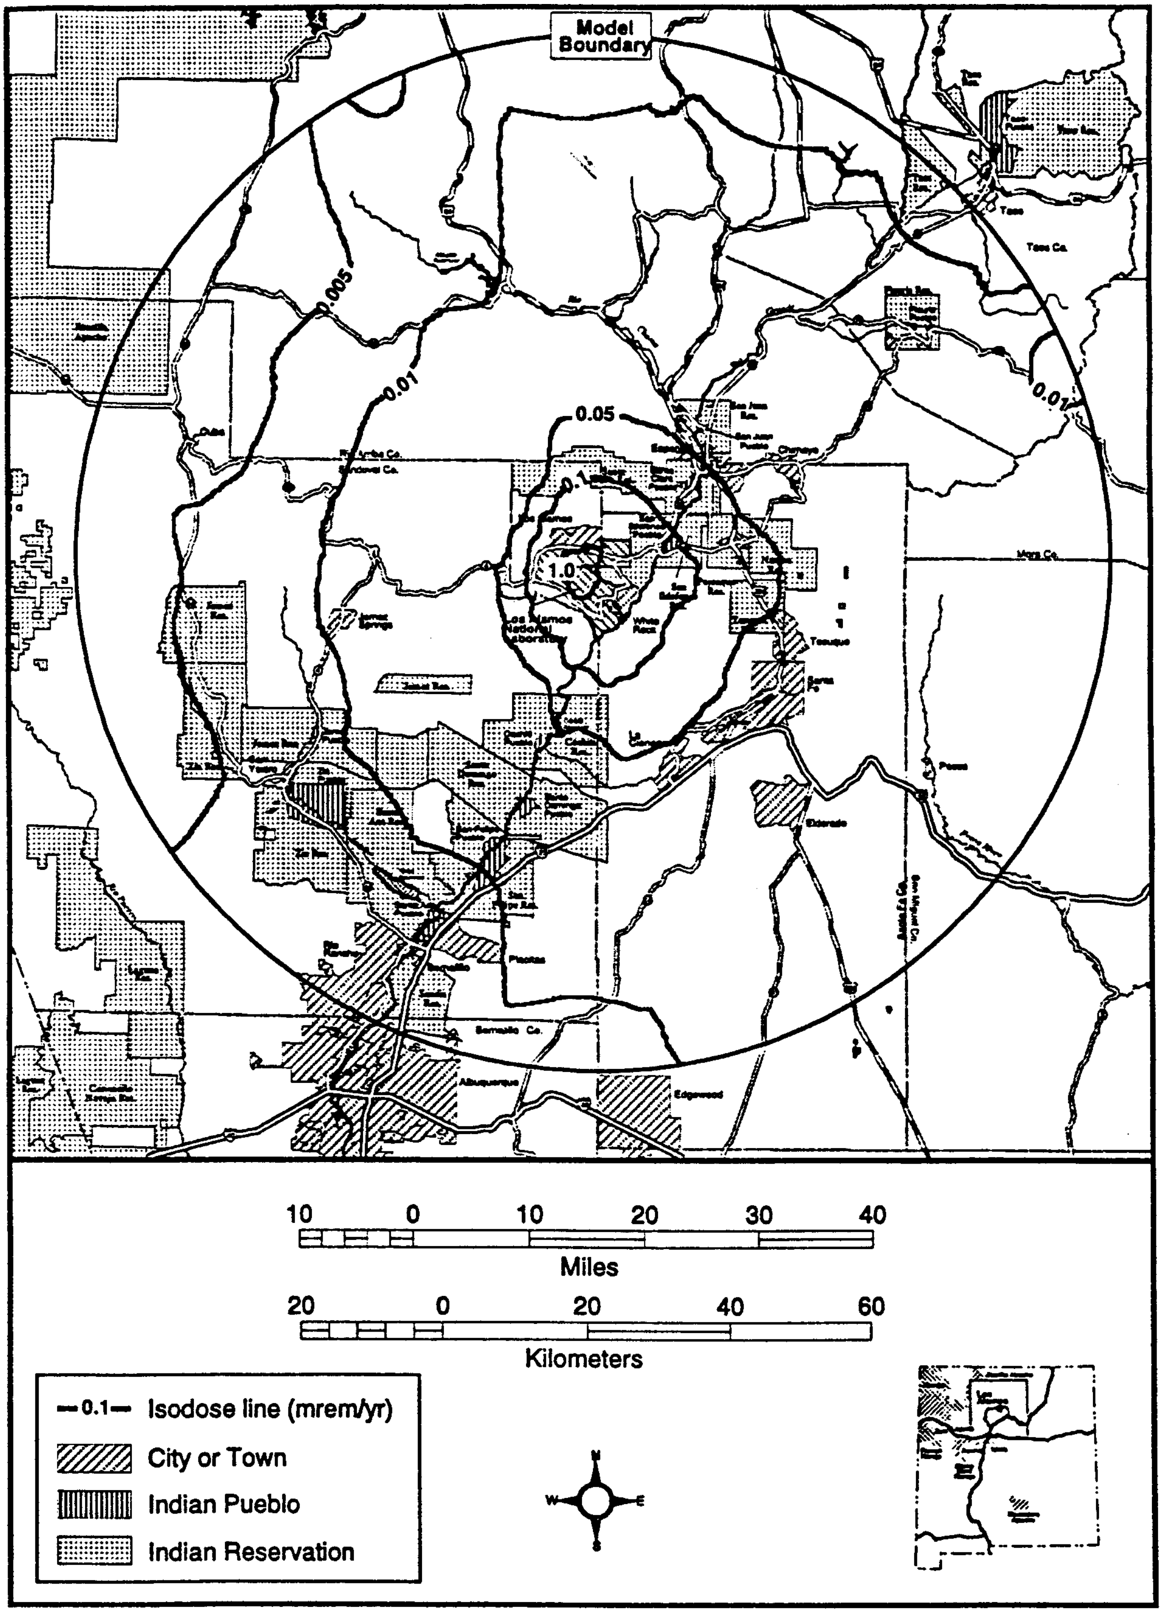

FIGURE 5.4.7–1.—*Isodose Lines from Airborne Releases for the Reduced Operations Alternative Within 50 Miles (80 Kilometers) of LANL.*

human health in minority or low-income communities (section 5.4.6.1).

As shown in section 5.4.10, impacts from on-site transportation and from LANL to U.S. 84/285 are estimated to be 0.0017 excess LCFs per year from incident-free transportation and 0.042 deaths and injuries per year from transportation accidents. Impacts from transportation on route segments that pass through minority or low-income communities (particularly the segment from U.S. 84/285 to I–25) are estimated to be 0.0018 excess LCFs per year from incident-free transportation and 0.095 deaths or injuries per year from transportation accidents. Therefore, no high and adverse impact is expected to either a member of the general public or to a member of a minority or low-income population due to transportation in the vicinity of LANL transportation routes.

5.4.8 Cultural Resources

Construction activities and explosive test activities under this alternative are essentially the same as those under the No Action Alternative. Because these are the activities with the most potential for impacts to cultural resources, impacts to prehistoric resources, historic resources, and TCPs under the Reduced Operations Alternative would be similar to those stated for the No Action Alternative in subsection 5.2.8, including the associated table. DOE would continue to manage and protect the 1,295 inventoried archaeological resources in compliance with the *Archaeological Resources Protection Act* (16 U.S.C. §470aa), Sections 3, 4, 6, and 7, and related legislation (see chapter 4). Management and protection of historic structures would be similar to that of the No Action Alternative (section 5.2.8).

Spiritual Entities

As with the No Action Alternative, no assessment of impacts to "unseen" or "spiritual" entities was attempted.

5.4.9 Socioeconomics, Infrastructure, and Waste Management

This section describes the social, economic, and infrastructure impacts of activities at LANL under the Reduced Operations Alternative.

5.4.9.1 *Socioeconomic Impacts*

Employment, Salaries, and Population

The primary (direct) impacts of this type are presented in Table 5.4.9.1–1 for the LANL workforce only. The secondary (indirect) impacts and the total population changes projected are presented in Table 5.4.9.1–2 for the Tri-County area. These changes are assumed to occur within a year of the ROD for the SWEIS.

Housing

The population changes anticipated in the Tri-County area, based on the total employment changes described above, are projected to result in a reduction in demand of 27 housing units. The distribution of this reduction in the three counties is: a reduction of 6 units in Los Alamos County; a reduction of 10 units in Rio Arriba County; and a reduction of 11 units in Santa Fe County.

A reduction in housing demand at these levels is not expected to exert any significant pressure on rents and house prices, and is not expected to effect apartment vacancies or turnover periods for house sales in any of these three counties.

Construction

Table 5.4.9.1–3 contains the results of the analysis of construction spending, labor salaries, and labor employment for the period fiscal year 1997 through fiscal year 2006. Construction activities associated with this alternative are expected to draw workers already present in the Tri-County area who

TABLE 5.4.9.1–1.—*Summary of Primary LANL Employment, Salaries[a], and Procurement Under the Reduced Operations Alternative[b]*

	LOS ALAMOS COUNTY	RIO ARRIBA COUNTY	SANTA FE COUNTY	TRI-COUNTY TOTAL	OTHER NEW MEXICO COUNTIES	NEW MEXICO TOTAL	OUTSIDE NEW MEXICO	TOTAL
Employees	4,821	1,913	1,832	8,566	607	9,173	174	9,347
Difference[c]	(14)	(6)	(5)	(25)	(1)	(26)	(2)	(28) (-< 1%)
Salaries ($M)	252.4	44.6	73.7	370.7	16.3	387	8.5	395.4
Difference[c]	(2.9)	(0.4)	(0.6)	(3.2)	0	(3.3)	(0.2)	(3.5) (- 1%)
Procurement ($M)	215.4	1.7	20.6	237.7	121.8	359.5	228.8	588.4
Difference[c]	(0.3)	0.0	(0.1)	(0.3)	(0.6)	(1.0)	(2.8)	(3.7) (- 1%)

( ) indicates a decrease as compared to baseline.
[a] Salaries are for UC employees only; subcontractor salaries (Johnson Controls, Inc.; Protection Technology of Los Alamos, etc.) are included in the procurement dollars.
[b] Reflects projected locations of employee residences and LANL procurement activities.
[c] Difference is as compared to fiscal year 1996. Percentage difference is shown in parentheses in the far right (TOTAL) column.

TABLE 5.4.9.1–2.—*Summary of Total Tri-County Employment, Salaries, Business Activity, and Population Changes Under the Reduced Operations Alternative*

	PRIMARY CHANGE	SECONDARY CHANGE	TOTAL TRI-COUNTY CHANGE	TRI-COUNTY PRIMARY WORKER CHANGE[a]	TRI-COUNTY SECONDARY WORKER CHANGE[b]	TOTAL TRI-COUNTY WORKER CHANGE	TOTAL TRI-COUNTY POPULATION CHANGE[c]
Employment/ Population	(25)	(43)	(68)	(20)	(13)	(33)	(64) (-< 1%)
Personal Incomes	($3 million)	($3 million)	($6 million) (-< 1%)				
Annual Business Activity	($0.3 million)	($0.7 million)	($1 million) (-< 1%)				

( ) indicates a decrease as compared to baseline. Percentages in parentheses are the percentage change that the number represents. These are provided for total population change, total person income change, and total annual business activity change.
[a] This is the number of direct workers moving to the Tri-County area, assuming that 80 percent of new LANL employees are from outside this area.
[b] This is the number of secondary workers moving to the Tri-County area, assuming that 30 percent of secondary employment is from outside this area.
[c] This is the total population increase in the Tri-County area, assuming that, on average, each worker moving to the area increases the population by 1.935 (and each worker leaving the area decreases the population by 1.935).

TABLE 5.4.9.1–3.—*Construction Spending, Labor Salaries, and Labor Employment Numbers Under the Reduced Operations Alternative (Fiscal Year 1997 Through 2006)*

YEAR	CONTRACT $M	LABOR $M	EMPLOYEES
1997	63	15	432
1998	187	45	1,282
1999	208	50	1,426
2000	219	53	1,502
2001	210	50	1,440
2002	120	29	823
2003	91	22	624
2004	90	22	617
2005	109	26	747
2006	108	26	741

$M = dollars given in millions
Sources: DOC 1996, PC 1997a, and PC 1997b

historically have worked from job to job in the region. Thus, this employment is not expected to influence socioeconomic factors.

Local Government Finance

Under this alternative, the Tri-County gross receipts tax yields would not be expected to change substantially (about a $100,000 decrease from the baseline yield).

Services

Annual school enrollment in the Tri-County area would decrease by 11 students. This enrollment change would have no discernible effect on classroom capacity. Annual funding assistance from the State of New Mexico could be reduced by about $44,000 because of these enrollment decreases.

The demand for police, fire, and other municipal services would not be expected to change substantially.

5.4.9.2 *Infrastructure Impacts*

Annual electricity use projected under the Reduced Operations Alternative is a total of 508 gigawatt-hours, 163 gigawatt-hours for LANSCE, and 345 gigawatt-hours for the rest of LANL. The peak electrical demand is projected to be 88 megawatts, 38 megawatts for LANSCE, and 50 megawatts for the rest of LANL[1]. The existing supply of electricity to the Los Alamos area is not sufficient year-round to meet the projected electrical peak demand for LANL operations under this alternative; thus, periods of brownouts are anticipated unless measures are taken to increase the supply of electricity to the area. (Sections 1.6.3.1 and 4.9.2 discuss ongoing efforts to increase electrical power supply to this area.) This situation is exacerbated by the additional electrical demand for BNM and the communities of Los Alamos and White Rock. (While these organizations did not provide use projections, their historical usage is reflected in section 4.9.2 of chapter 4.)

Natural gas use is projected to be 1,840,000 decatherms annually, the same as projected under the No Action Alternative. Demand should continue to be dominated by heating requirements.

Water use projected under the Reduced Operations Alternative is a total of 602 million gallons (2,279 million liters) per year, 108 million gallons (409 million liters) per year for LANSCE, and 494 million gallons (1,870 million liters) per year for the rest of LANL. This is well within DOE water rights, about 1,806 million gallons (6,836 million liters) per year; however, this water right also provides for water used by Los Alamos County and BNM. Based on existing information regarding non-LANL water use, the water

1. These values include the proposed SCC Project annual electricity and peak electrical demand for a 50-TeraOp operation and are reflected in all the alternatives. The SCC project was as an interim action to the SWEIS.

demands of this community can be met within the existing water rights (water demand is also discussed in section 5.4.3). The peak water requirements are the same as identified under the No Action Alternative.

5.4.9.3 *Waste Management*

The annual and 10-year total generation projections for radioactive and hazardous waste are reflected in Table 5.4.9.3–1. Radioactive liquid waste is not projected by facility because measurements of individual contributions are not made for all facilities. The total amount of radioactive liquid waste projected for receipt at TA–50 is 53 million gallons (200 million liters) over 10 years (or an average of 5.3 million gallons [20 million liters] per year) for this alternative. These projections include waste from key facilities, all other LANL facilities, waste management facilities, the ER Project, and construction activities.

Due to the reduced level of operations under this alternative, this alternative generates less waste than is generated under the No Action Alternative. As with the No Action Alternative, much of LANL's LLW, TRU, and chemical waste would be treated and packaged to meet waste acceptance criteria and shipped off the site for disposal; nondefense TRU waste from other sites would be stored at LANL pending the development of disposal options. Off-site disposal capabilities are much greater than the waste volumes generated at LANL.

5.4.9.4 *Contaminated Space*

The activities reflected in the Reduced Operations Alternative are projected to increase the total contaminated space at LANL by 63,000 square feet (5,853 square meters) over the next 10 years (the same as the No Action Alternative), as compared to the baseline established for this SWEIS as of May 1996 (chapter 4, section 4.9). The majority of this increase is due to implementation of actions that have already been reviewed under NEPA, but which had not been implemented at the time the baseline was established (the same ones discussed in the No Action Alternative).

5.4.10 Transportation

The transportation impacts projected for the Reduced Operations Alternative are summarized in this section. More detailed information regarding these impacts is included in volume III, appendix F. Although the number of many types of operational shipments associated with the Reduced Operations Alternative are lower than in the other alternatives, the number of LLW shipments for off-site disposal increases substantially as compared to the number of LLW shipments under the No Action Alternative (because the Reduced Operations Alternative reflects off-site disposal of most LLW). Due to the larger number of LLW shipments under this alternative, the total number of shipments of radioactive materials under the Reduced Operations Alternative is actually larger than the number of such shipments under the No Action Alternative (although this is still fewer shipments than are associated with the Expanded Operations or Greener Alternatives). For this reason, the transportation impacts associated with off-site radioactive shipments under the Reduced Operations Alternative are actually greater than the impacts associated with such shipments under the No Action Alternative (this is not true for off-site radioactive materials accidents because LLW transportation accidents are not among the bounding accidents).

5.4.10.1 *Vehicle-Related Risks*

Truck Emissions in Urban Areas

For the Reduced Operations Alternative, the projected risk is 0.034 excess LCF per year. Use of the Santa Fe Relief Route would have a very small effect on this risk (it would change to

TABLE 5.4.9.3–1.—*Projected Annual and 10-Year Total Waste Generation Under the Reduced Operations Alternative*[a]-Continued

NA indicates that this facility does not routinely generate these types of waste.

[a] Radioactive liquid waste generation is not projected by facility (section 5.4.9.3).

[b] The chemical waste numbers reflect waste that exhibits a hazardous characteristic (ignitability, corrosivity, reactivity, or toxicity), is listed as a hazardous waste by EPA, is a mixture of listed hazardous waste and solid waste, or is a secondary waste associated with the treatment, storage, or disposal of a hazardous waste. This includes waste that is subject to regulation under RCRA, as well as PCB waste and asbestos waste regulated under *Toxic Substances Control Act*. This waste category also includes biomedical waste.

[c] These projections include 141,000 cubic feet (4,000 cubic meters) of LLW due to backlogged waste.

[d] These LLW projections include 141,000 cubic feet (4,000 cubic meters) of LLW generation anticipated due to the CMR Building Upgrades, Phase II.

[e] These projections reflect reduced operational waste generation during construction activities that are included in this alternative.

[f] These projections include 22,000 pounds (10,000 kilograms) of chemical waste, 550 pounds (250 kilograms) of biomedical waste (a special form of chemical waste), 1,560 cubic feet (44 cubic meters) of LLW, and 850 cubic feet (24 cubic meters) of LLMW associated with ongoing efforts to remove obsolete and contaminated equipment.

[g] These facilities provide for storage, treatment, and disposal of waste generated throughout LANL. These activities generate secondary waste, the quantities of which are reflected in this table for these facilities.

[h] The ER Project is projected to generate 390 cubic feet (11 cubic meters) per year of TRU and mixed TRU waste together. All of this waste is presented under the TRU waste columns.

[i] Grand totals have been rounded.

0.033 excess LCF per year). The only difference is that the Santa Fe Relief Route would have 1.2 miles (1.9 kilometers) less of urban highway mileage. Approximately 65 percent of the excess LCFs are due to radioactive material shipments and 35 percent are due to hazardous chemical shipments. All shipments are conservatively assumed to result in an empty truck making the return trip. This is appropriate for WIPP and LLW shipments and for many SST shipments; however, most shipments are in general commerce and would not include the return of an empty truck.

Truck Accident Injuries and Fatalities

The impacts projected for the Reduced Operations Alternative are presented in Table 5.4.10.1–1. (Additional information is provided in volume III, appendix F, section F.6.3.) Use of the Santa Fe Relief Route would reduce the risks of accidents, injuries, and fatalities by almost one-half of those indicated for the segment from U.S. 84/285 to I–25 due to the assumption that the accident rate on the Santa Fe Relief Route would be much lower than for the route through Santa Fe. Approximately 65 percent of the impacts are due to radioactive material shipments and 35 percent are due to hazardous chemical shipments. Again, all shipments are assumed to result in a return by an empty truck.

5.4.10.2 *Cargo-Related Risks*

Incident-free Radiation Exposure

The incident-free radiation exposure impacts projected for the off-site shipments under the Reduced Operations Alternative are presented in Table 5.4.10.2–1; as noted in section 5.2.10.2, the total is the dose throughout the U.S. and is dominated by the segments outside of New Mexico. The aircraft segment is for overnight carrier service; the truck segment to and from the airport is included in the truck results. In general, use of the Santa Fe Relief Route would result in only small changes in this type of impact. Truck crew doses and nonoccupational doses for people at rest stops would increase due to the increased length of the Santa Fe Relief Route for north-bound shipments carrying the radioactive material. Nonoccupational doses for people sharing the road would decrease due to the lower traffic density projected for the relief route.

MEI dose occurs between LANL and I–25 and is 0.00032 rem.

Driver Doses from On-Site Shipments of Radioactive Materials

The projected collective radiation dose for LANL drivers under the Reduced Operations Alternative is 4.262 person-rem. This collective dose would be expected to result in 0.0017 excess LCFs among these drivers.

The average individual driver dose is projected to be 0.178 rem per year, which is well below the DOE radiation protection limit of 5 rem per year.

Transportation Accidents

The following discussion addresses the potential impacts of accidents leading to the release of either radioactive or hazardous material being transported in support of LANL operations under the Reduced Operations Alternative. Results are given for both off-site and on-site shipments.

Off-Site Radioactive Materials Shipments

MEI doses calculated with RADTRAN do not vary by alternative and are given in Table 5.2.10.2–2. The population dose and corresponding excess LCF per year for these shipments are presented in Table 5.4.10.2–2 for these accidents. ADROIT results that are separated into frequency and consequence components are not readily available. The product, MEI dose risk, can be presented in

TABLE 5.4.10.1–1.—*Truck Accident Injuries and Fatalities Projected for LANL Shipments Under the Reduced Operations Alternative*

Remainder of New Mexico	0.031	0.012	0.000025	4×10^{-7}	4×10^{-6}	0.043	0.000022
Rest of U.S.	2.5	NA	NA	4×10^{-6}	0.00001	2.5	0.0012

NA = Not applicable

terms of excess LCF per year; for the Reduced Operations Alternative, MEI dose risk due to plutonium-238 oxide and due to pit shipments were each less than 1×10^{-10} excess LCF per year.

The use of the Santa Fe Relief Route would reduce the projected population dose (and therefore the excess LCFs per year) to about one-third for the U.S. 84/285 to I–25 segment, as compared to use of the route through Santa Fe. This difference is primarily due to the difference in population density along these routes. (The lower traffic density along the relief route is also a factor.) The use of the Santa Fe Relief Route would increase the projected population dose (and therefore excess LCFs per year) for the remainder of New Mexico segment to about double that identified if the route through Santa Fe is used. This difference is due to the increase (6 miles [9.6 kilometers] more) in the distance traveled on I–25 for north-bound shipments.

On-Site Radioactive Materials Shipments

The MEI doses, frequencies, and MEI risks due to the bounding on-site shipments involving radioactive materials are given in Table 5.4.10.2–3. As noted in section 5.2.10.2, the frequency of the bounding DARHT and PHERMEX shipments has been added to the frequency of irradiated target shipments.

TABLE 5.4.10.2–3.—*MEI Doses and Frequencies for Bounding On-Site Radioactive Materials Accidents Under the Reduced Operations Alternative*

SHIPMENT TYPE	EVENT FREQUENCY PER YEAR	MEI DOSE	MEI RISK
Plutonium-238 Solution	8.8×10^{-8}	8.7 rem	7.7×10^{-7} rem/year (3.1×10^{-10} excess LCF/year)
Irradiated Targets	2.9×10^{-6}	acute fatality	2.9×10^{-6} fatalities/ year

Hazardous Materials Shipments

The bounding hazardous materials shipments for accident analyses are major chlorine shipments (toxic), major propane shipments (flammable), and major explosive shipments. The consequences of an accident involving a major explosive shipment is bounded by the consequences of an accident involving a major propane shipment, so the frequency of explosives shipments was added to the frequency of propane shipments (rather than analyzing them separately).

Accidental Chlorine Release

The projected frequencies, consequences, and risks associated with major chlorine accidents under the Reduced Operations Alternative are presented in Table 5.4.10.2–4.

The use of the Santa Fe Relief Route would result in about one-tenth the risk of fatalities and injuries on the U.S. 84/285 to I–25 segment, as compared to the use of the route through Santa Fe. These differences are due to the lower population density along the Santa Fe Relief Route. The use of the Santa Fe Relief Route would result in a slight increase in the risk of fatalities and injuries on the remainder of New Mexico segment because of the extra 6 miles (9.6 kilometers) traveled on I–25 for northbound traffic (chlorine shipments are all assumed to travel north on I–25).

Accidental Propane Release

The projected frequencies, consequences, and risks associated with major propane accidents under the Reduced Operations Alternative are presented in Table 5.4.10.2–5.

The use of the Santa Fe Relief Route would result in about one-third the risk of fatalities and one-fourth the risk of injuries on the U.S. 84/285 to I–25 segment, as compared to the use of the route through Santa Fe. These differences are due to the lower population density along the Santa Fe Relief Route. The use of the Santa Fe Relief Route would result in a slight decrease in the risk of injuries and fatalities on the Remainder of New Mexico segment because of the 6-mile (9.6-kilometer) reduction in distance traveled on I–25 for southbound traffic (propane shipments are all assumed to travel south on I–25).

5.4.11 Accident Analysis

Transportation accidents for the Reduced Operations Alternative are addressed in section 5.4.10. High-frequency (greater than 1 in 100) occupational accidents for the Reduced Operations Alternative are addressed in section 5.4.6.

5.4.11.1 *Multiple Source Release of Hazardous Material from Site-Wide Earthquake and Wildfire*

The risks from these accidents are driven primarily by the frequency and magnitude of the earthquakes and wildfires in the area. Because the same types of operations will be conducted in the same facilities and the inventories of MAR will be about the same, there are no substantial changes in risk from earthquakes between the No Action and the Reduced Operations Alternatives.

For the wildfire scenario, the frequency will remain the same, but the MAR will be reduced by about 25 percent at TSTA, reducing the consequences by approximately 1 percent (6 person-rem) compared to the No Action Alternative. Table 5.2.11.1–1 and 5.2.11.1–2 can be referenced for the results of the No Action Alternative.

TABLE 5.4.10.2–4.—*Frequencies, Consequences, and Risk for a Major Chlorine Accident Under the Reduced Operations Alternative*

[a] Because individual factors were rounded for presentation, multiplication of the factors on this table may not exactly match the results in these columns.

5.4.11.2 *Plutonium Releases from Manmade and Process Hazards at LANL*

For the Reduced Operations Alternative, the frequencies and consequences of these accidents are the same as under the No Action Alternative. These are presented in Table 5.2.11.2–1.

An overview of the 1969 plutonium fire at the Rocky Flats site and a comparison of the design and operational differences between Rocky Flats and TA–55–4 are presented in volume III, appendix G, section G.4.1.2.

Substantial differences exist between the nuclear facility and operations being conducted in TA–55–4 today and those that were present at the Rocky Flats Plant in 1969. TA–55–4 was designed to correct the deficiencies detected in older facilities such as the Rocky Flats Plant and is being upgraded to meet the even more stringent requirements of the 1990's, including enhanced seismic resistance and fire containment.

5.4.11.3 *Highly Enriched Uranium Release from Process Hazard Accident*

As discussed in section 5.2.11.3, this accident is the dominant accident for release of HEU. Because there are no planned changes in the number of experiments or the inventories associated with this activity, the frequency and consequences of this scenario under the Reduced Operations Alternative are the same as presented under the No Action Alternative. These are reflected in Table 5.2.11.3–1.

5.4.11.4 *Tritium Release from a Manmade Hazard Accident at LANL*

As presented in section 5.2.11.4, the aircraft crash event is the dominant accident that involves tritium. Because no changes in operations or inventories from the No Action Alternative are made, the consequences and frequencies associated with these scenarios are the same as those presented in Table 5.2.11.4–1.

5.4.11.5 *Chemical Releases from Manmade and Process Hazard Accidents at LANL*

For the chlorine releases, on-site personnel could be exposed to concentrations in excess of ERPG–2. Chlorine has a highly objectionable odor, which prompts sheltering and escape; however, personnel can be quickly overcome when exposed to high concentrations.

The number of accidental releases of chlorine depends upon the number of times the material is handled. The minor changes in activity levels cause the risk to decrease by about 5 to 10 percent. The incremental risk for this alternative over the No Action Alternative is essentially zero. These changes do not alter the overall risk profile for the site or substantially alter the relative ranking of each of these accidents. These results are provided in Tables 5.4.11.5–1 and 5.4.11.5–2.

5.4.11.6 *Worker Accidents*

Because there are no changes in the types of activities, frequencies, or inventories from the No Action Alternative, an individual worker is subject to the same risk, as presented in Table 5.2.11.6–1.

TABLE 5.4.11.5–1.—*Summary of Chlorine Exposure Scenarios at LANL—Reduced Operations Alternative*

SCENARIO DESCRIPTION	LIKELIHOOD[a]	CONSEQUENCE MEASURES[b,c]	SOCIETAL RISK (NUMBERS AT OR ABOVE ERPG–2 PER YEAR)
PROCESS HAZARD ACCIDENTS			
CHEM–01 Chlorine release (150 pounds [68 kilograms]) from potable water treatment station, due to human error during cylinder changeout or maintenance, or due to random hardware failures.	Approximately 0.0011 per year (i.e., one such event in approximately 900 years)	For the risk-dominant large leak scenario, an average of approximately 43 persons exposed above ERPG–2 levels, and approximately 12 persons exposed above ERPG–3 levels, to distances of up to a few tenths of a mile.	0.047 The Reduced Operations Alternative is 5% less likely than the No Action due to the handling of one less chlorine cylinder; no change in severity.
CHEM–02 Multiple cylinder (1,500 pounds [680 kilograms]) from toxic gas storage shed at Gas Plant, due to fire or aircraft crash.	Approximately 0.00012 per year (i.e., one in approximately 8,500 years)	Average of 292 people within LANL (ranging from none to 1,000 depending upon wind direction) exposed at or above ERPG–2 or –3 levels; town protected by canyon from highest concentrations.	0.035 Frequency increases by 8% from the No Action Alternative; no change in severity.
CHEM–03 Chlorine release (150 pounds [68 kilograms]) from toxic gas storage shed at Gas Plant, due to random failure or human errors during cylinder handling.	Approximately 0.00012 per year (i.e., one in approximately 8,000 years)	An average of approximately 263 exposed above ERPG–2 levels; or 239 above ERPG–3 levels, at distances to a fraction of a mile, all within LANL; town protected by canyon from highest concentrations.	0.032 No change in likelihood or severity over the No Action Alternative.
CHEM–06 Chlorine gas release outside Plutonium Facility.	Approximately 0.063 per year (i.e., one event in approximately 16 years)	Average number exposed at or above ERPG–2 doses is approximately 102, and above ERPG–3, approximately 7 at ranges to a fraction of a mile.	6.426 No change in likelihood or severity over the No Action Alternative.

[a] Accident likelihood estimates are conservative, given the information available. However, for the particularly unlikely accidents, it is possible that there are causal mechanisms that were missed, so the possibility of a more probable scenario cannot be rigorously ruled out.

[b] Conservative assumptions have been employed in estimating the quantity and form of the hazardous materials available for release.

[c] Accident consequences are generally conservative (pessimistic), but do not bound the effects of accidents occurring under unusually unfavorable weather conditions. The results quoted are weather averaged.

TABLE 5.4.11.5–2.—*Summary of Chemical Exposure Scenarios—Reduced Operations Alternative*

SCENARIO	DESCRIPTION	LIKELIHOOD[a]	CONSEQUENCE MEASURES[b,c]	SOCIETAL RISK (NUMBERS AT OR ABOVE ERPG–2 PER YEAR)
CHEM–04	Bounding single container release of toxic gas (selenium hexafluoride) from waste cylinder storage.	Approximately 0.004 per year (i.e., one in about 250 years)	Average number of off-site persons exposed above ERPG–2 level is zero; toxic effects generally limited to the source's TA (TA–54).	0 No changes in frequency or severity from the No Action Alternative.
CHEM–05	Bounding multiple cylinder release of toxic gas (sulfur dioxide) from waste cylinder storage.	Approximately 0.00014 per year (i.e., one event in approximately 7,000 years)	Under conservative daytime conditions, no one outside the source area (TA–54) would see levels above ERPG–2. Under least favorable conditions, 13 persons could be exposed above ERPG–3 levels.	0 No changes in frequency or severity from the No Action Alternative.

[a] Accident likelihood estimates are conservative, given the information available. However, for the particularly unlikely accidents, it is possible that there are causal mechanisms that were missed, so the possibility of a more probable scenario cannot be rigorously ruled out.
[b] Conservative assumptions have been employed in estimating the quantity and form of the hazardous materials available for release.
[c] Accident consequences are generally conservative (pessimistic), but do not bound the effects of accidents occurring under unusually unfavorable weather conditions. The results quoted are weather averaged.

5.5 IMPACTS OF THE GREENER ALTERNATIVE

5.5.1 Land Resources

5.5.1.1 *Land Use*

Changes to land use under the Greener Alternative would be the same as for the No Action Alternative.

5.5.1.2 *Visual Resources*

Changes to visual resources under the Greener Alternative would be the same as for the No Action Alternative.

5.5.1.3 *Noise*

Changes to noise levels and air blasts associated with high explosives testing under the Greener Alternative would be the same as for the No Action Alternative. The overall LANL on-site activities (due to the increased operational levels in activities not related to weapons) would increase under implementation of the Greener Alternative resulting in an overall greater total number of noise producing events for workers. This could be a slight negative impact to the worker noise environment, as compared to the No Action Alternative.

5.5.2 Geology and Soils

Potential impacts for the Greener Alternative on geology and soils would be the same as those for the No Action Alternative.

5.5.3 Water Resources

5.5.3.1 *Surface Water*

Table 5.5.3.1–1 shows the total flow from the NPDES outfalls for each of the major watersheds under the Greener Alternative. In volume III, appendix A, Table A.1–1 presents more detailed information on the NPDES outfalls for all four alternatives by facility (key and non-key), watershed, and location. The estimated total gallons discharged into all watersheds totals 275 million gallons (1,041 million liters) under the Greener Alternative. This is an increase from the index effluent volume of 233 million gallons (882 million liters).

NPDES outfall effluent quality during the period of the SWEIS (1997 through 2006) is expected to be the same under this alternative as described for the No Action Alternative, including the radionuclide concentrations in effluent from TA–50, as presented in Table 5.2.3–2. The canyons with increased NPDES outfall flows (Los Alamos and Sandia) are the same as the No Action and the Expanded Operations Alternatives. The increased flow volumes in these two canyons are the same as the Expanded Operations Alternative, and the potential impacts should be minimal for the same reasons as discussed in the No Action and the Expanded Operations Alternatives. For the Greener Alternative, there are no new activities that will result in changes to stormwater runoff.

5.5.3.2 *Alluvial Groundwater*

The NPDES outfall discharges are similar to those under Expanded Operations and are expected to result in similar alluvial groundwater volumes.

The projected discharge from the RLWTF into Mortandad Canyon under the Greener Alternative is 6.6 million gallons (25 million liters) per year, as compared to the RLWTF index volume of 5.5 millions gallons (21 million liters) per year.

The new HELWTF will result in improved water quality to Canyon de Valle as discussed under the No Action Alternative.

Totals	87	55	103.6	132.3	129.6	142.0	233.2	274.9

MGY: millions of gallons per year

[a] NPDES Information Sources: Index information was provided by the Surface Water Data Team Reports of August 1996 (Bradford 1996) and as modified in 1997 (Garvey 1997). Outfall flow projections for the alternatives were based on the outfalls remaining as of November 1997. Additional outfalls may be eliminated in the future, as discussed in the *Environmental Assessment for Effluent Reduction* (DOE 1996e), as well as several other outfalls that may be closed as part of LANL's ongoing outfall reduction program.

5.5.3.3 *Perched Groundwater*

Groundwater flow and contaminant pathways to the intermediate perched groundwater bodies are not well characterized nor understood. It is possible that the increased NPDES discharges to Los Alamos and Sandia Canyons under this alternative could increase recharge of the intermediate perched groundwater and contaminant transport beneath these canyons.

5.5.3.4 *Main Aquifer*

Recharge mechanisms to the main aquifer are uncertain. However, for the same reasons as discussed under the No Action Alternative, impacts resulting from increased NPDES outfall flows under the Greener Alternative should be negligible.

A conservative projection of LANL water use under the Greener Alternative is 759 million gallons (2,873 million liters) per year. Los Alamos County and the NPS did not provide projections, but in 1994 the County used about 958 million gallons (3,626 million liters) from this water right and the NPS used about 5 million gallons (19 million liters). Based on this information, it is expected that the water requirements of this community can be met within the existing water rights from the main aquifer; however, projected use may approach 100 percent of the existing water rights to the main aquifer under this alternative.

For the purposes of modeling drawdown of the main aquifer, annual water use projections were made. The total water usage from DOE water rights was projected to average 1,670 million gallons (6,321 million liters) per year under the Greener Alternative, with a maximum annual use of 1,697 million gallons (6,423 million liters) and a minimum annual use of 1,611 million gallons (6,098 million liters).

The model results reflect water level changes at the top of the main aquifer across the alternatives, given continued draw from the aquifer by DOE, Española, and Santa Fe. Table 5.5.3.4–1 shows predicted water level changes at the surface of the main aquifer during the period from 1997 through 2006 for the Greener Alternative; as noted in section 5.2.3.1, these changes are not all due to LANL operations. Although the water use modeled includes water use in Española and Santa Fe, the differences between the alternatives are due only to LANL operations. The impacts to the volume of water in the main aquifer under this alternative are very similar to those described for the No Action Alternative; the drawdowns in DOE well fields are minimal relative to the total thickness of the main aquifer, and the volume of water to be used over the period from 1997 through 2006 is negligible relative to the volume of water in storage. Details of the conceptual model, assumptions, uncertainties and limitations, and input parameters for the groundwater model are described in volume III, appendix A.

5.5.4 Air Quality

5.5.4.1 *Nonradiological Air Quality Impacts*

Criteria pollutant emissions under the Greener Alternative are less than those under the Expanded Operations Alternative. Because the bounding analysis of criteria pollutant emissions for all alternatives (based on the emissions under the Expanded Operations Alternative) results in estimated concentrations of each pollutant below the standards established to protect human health with an ample margin of safety, criteria pollutant emissions under the Greener Alternative would also be below these levels.

As discussed in section 5.1.4, the only toxic air emissions with the potential to impact human

TABLE 5.5.3.4–1.—*Maximum Water Level Changes at the Top of the Main Aquifer Under the Greener Alternative (1997 Through 2006)*

WATER LEVEL CHANGE IN FEET[a,b]

Household, Community Wells	0.0

[a] Negative value (-) indicates water level drop; positive value (+) indicates water level rise.

[b] Also, the water level changes projected by the regional MODFLOW model represent average changes over a whole grid-cell (i.e., a square that is a mile on a side). They are, for the most part, not predictive of the water level changes at any single point within the cell (for example, a supply well). Pumping wells have characteristic “cones of depression” where the water surface reflects an inverted cone, and water levels at the well may be quite different from levels even a few ten’s of feet away. Whether any individual well would exhibit water level changes consistent with the predicted grid-cell average change is a function of, for example, its location within the grid-cell; proximity to other pumped wells; and the individual well operation, construction, and hydraulics. Hence, the water level changes predicted by the model can only be considered qualitatively and cannot be considered as finite changes.

health and the environment under any alternatives are those associated with HEFS operations and the additive emissions from all the pollutants from all TAs on receptor sites located near the Los Alamos Medical Center. Under the Greener Alternative, such emissions are projected to be similar to those addressed in the No Action Alternative (section 5.1.4). Therefore, pollutants released from LANL operations under the Greener Alternative are not expected to cause air quality impacts that would affect human health and the environment.

5.5.4.2 *Radiological Air Quality Impacts*

This section addresses the radiation dose to the FS MEI, LANL MEI, and the population dose from LANL radionuclide air emissions under the Greener Alternative.

Facility-Specific Maximally Exposed Individual

Table 5.5.4.2–1 shows the FS MEI for each facility analyzed under the Greener Alternative. The highest MEI dose was 4.52 millirems per year, which is 45.2 percent of the regulatory limit for the air pathway. The EPA regulatory limit would not be exceeded from emissions of these facilities under the Greener Alternative.

TABLE 5.5.4.2–1.—*Facility-Specific Information—Greener Alternative*

FACILITY	DOSE[a] (MREM/YR)
TA–3–29 (CMR)	0.35
TA–3–66 (Sigma)	0.35
TA–3–102 (Shops)	0.28
TA–11 (High Explosive Testing)	0.31
TA–15/36 (Firing Sites)	2.17
TA–16 (Tritium Facility)	0.31
TA–18 (Pajarito Site)	1.93
TA–21 (Tritium Facility)	1.54
TA–48 (Radiochemistry Laboratory)	1.64
TA–55 (Plutonium Facility)	1.64
TA–53 (LANSCE)[b]	4.52
TA–54 (Boundary)[c]	0.79
TA–54 (White Rock)	0.45

[a] For each FS MEI, the total dose was calculated by adding the contributions from each modeled facility. An MEI does not leave or take protective measures.
[b] This is also the LANL MEI. Five specific sources were modeled from TA–53. These include the TA–53 ES–2, ES–3, IPF, LEDA and combined diffuse emissions.
[c] Two FS MEI locations were considered for TA–54 because Area G is bordering San Ildefonso Pueblo land. The first is a MEI location at the LANL boundary, 1,197 feet (365 meters) northeast of Area G. No person from the Pueblo currently is known to live along this boundary. The second is an actual MEI location in the town of White Rock, approximately 5,331 feet (1,625 meters) southeast of Area G.

LANL Maximally Exposed Individual

The location of the LANL MEI (2,625 feet [approximately 800 meters] north-northeast of TA–53) was shown to be identical to the FS MEI with the highest dose under this alternative. The LANL MEI dose was calculated to be 4.52 millirems per year under the Greener Alternative.

Population Dose

The collective dose to the population living within a 50-mile (80-kilometer) radius from LANL was calculated for emissions from all key facilities and found to be 13.79 person-rem per year. TA–15/36 account for 51.3 percent of this dose, and collectively, collective diffuse emissions, including those from these TAs, account for 52.1 percent of this dose. The values reported for population doses for this alternative, as well as the other alternatives, is higher than has been reported in the recent annual environmental reports. It is important to recognize that the alternatives analyzed represent increased operations when compared to recent history. The material throughput at the different facilities under the various alternatives is presented in chapter 3, section 3.6.

Isodose Maps

The isodose maps for the 50-mile (80-kilometer) region are shown on the isodose maps in Figures 5.5.4.2–1 and 5.5.4.2–2.

5.5.5 Ecological Resources, Biodiversity, and Ecological Risk

Impacts to ecological resources and biodiversity resulting from the Greener Alternative would not vary appreciably from those of the No Action alternative. There would not be any incremental changes from the No Action level of ecological risk.

5.5.6 Human Health

The consequences of implementing the Greener Alternative on public health and worker health are presented below. As discussed in section 5.1.6, "risk," as used in the SWEIS human health analysis, refers to the probability of toxic or cancer mortality under the specific exposure scenarios analyzed.

5.5.6.1 *Public Health*

The consequences of continued operations of LANL on public health under the Greener Alternative are presented below for the same topics discussed in section 5.2.6.1.

Regional Consequences of Airborne Radioactivity Inhalation and Immersion

The LANL MEI was estimated to be 2,625 feet (approximately 800 meters) north-northeast of LANSCE (TA–53). This location is within the LANL reservation, and the dose at this location is estimated to be 4.5 millirem per year (section 5.5.4.2), corresponding to a 72-year lifetime dose of 320 millirem. This location borders the Los Alamos townsite and is a conservative estimate for an MEI from LANL emissions. The background (TEDE) dose in the Los Alamos area is estimated to be 360 millirem per year; thus, the dose is 1.3 percent of the background dose.

Table 5.5.6.1–1 summarizes the LANL MEI dose and presents the corresponding excess risk of excess LCF to the MEI. These risks are presented on a lifetime basis, assuming that the hypothetical LANL MEI received the estimated dose of 4.5 millirem each year for a 72-year life. The excess LCF risk was estimated to be 0.0002 over a lifetime.

The isodose maps showing both the estimated dose near LANL and within a 50-mile (80-kilometer) radius of LANL are given in Figures 5.5.4.2–1 and 5.5.4.2–2. The population dose within the 50-mile (80-kilometer) radius is also given in Table 5.5.6.1–1, estimated to be 13.8 person-rem per year. As reflected in the table, the annual operations excess LCF risk was estimated to be 0.0069.

In the Greener Alternative, there are six facilities with FS MEIs receiving a dose that would exceed 1 millirem per year (volume III, appendix B):

- LANSCE, 4.52 millirem per year to the facility MEI
- HE Testing Sites (TA–15 and TA–36), 2.17 millirem
- Pajarito Site (TA–18), 1.93 millirem
- Radiochemistry Laboratory (TA–48), 1.64 millirem
- Plutonium Facility, 1.64 millirem
- TSTA and TSFF (TA–21), 1.54 millirem

External Radiation: Two Special Cases

As discussed in section 5.2.6.1, one contribution to public dose results from jogging or hiking the access road north of TA–21 and is attributable to cesium-137 known to be on the ground within the TA. The MEI dose is not expected to change

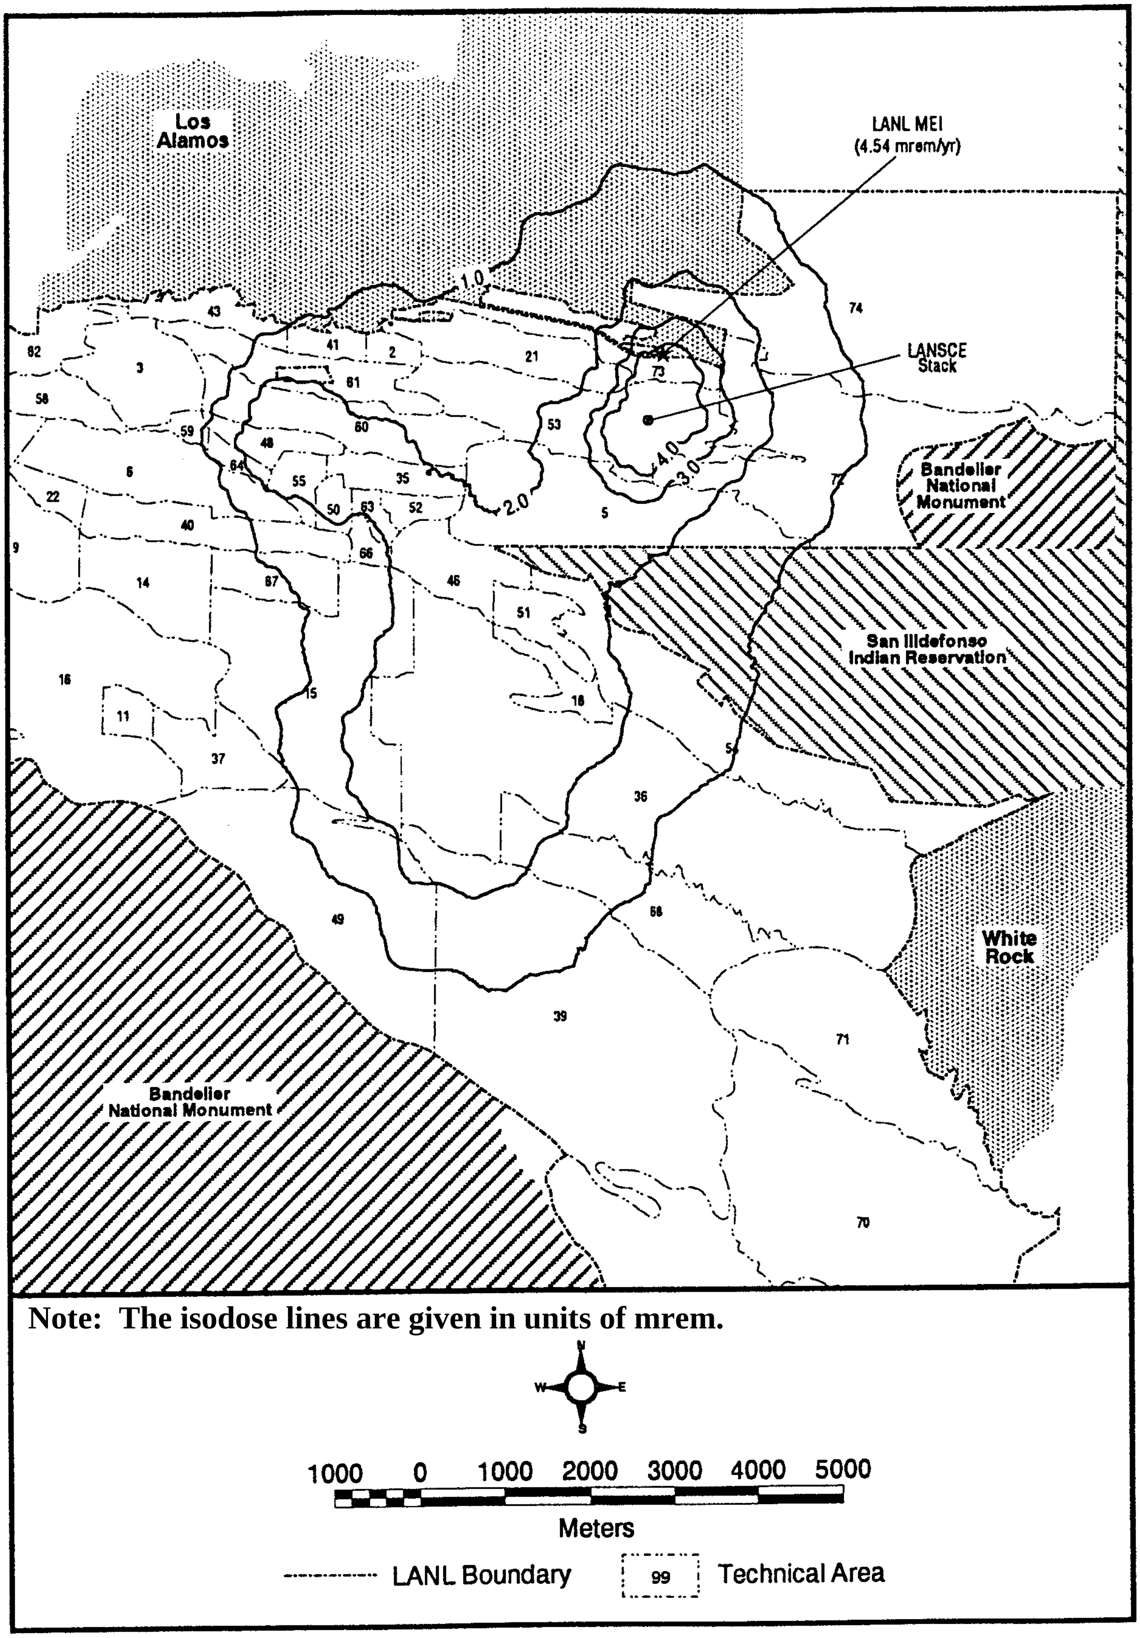

FIGURE 5.5.4.2–1.—*Isodose Map Showing Doses Greater Than 1 Millirem per Year for the Greener Alternative.*

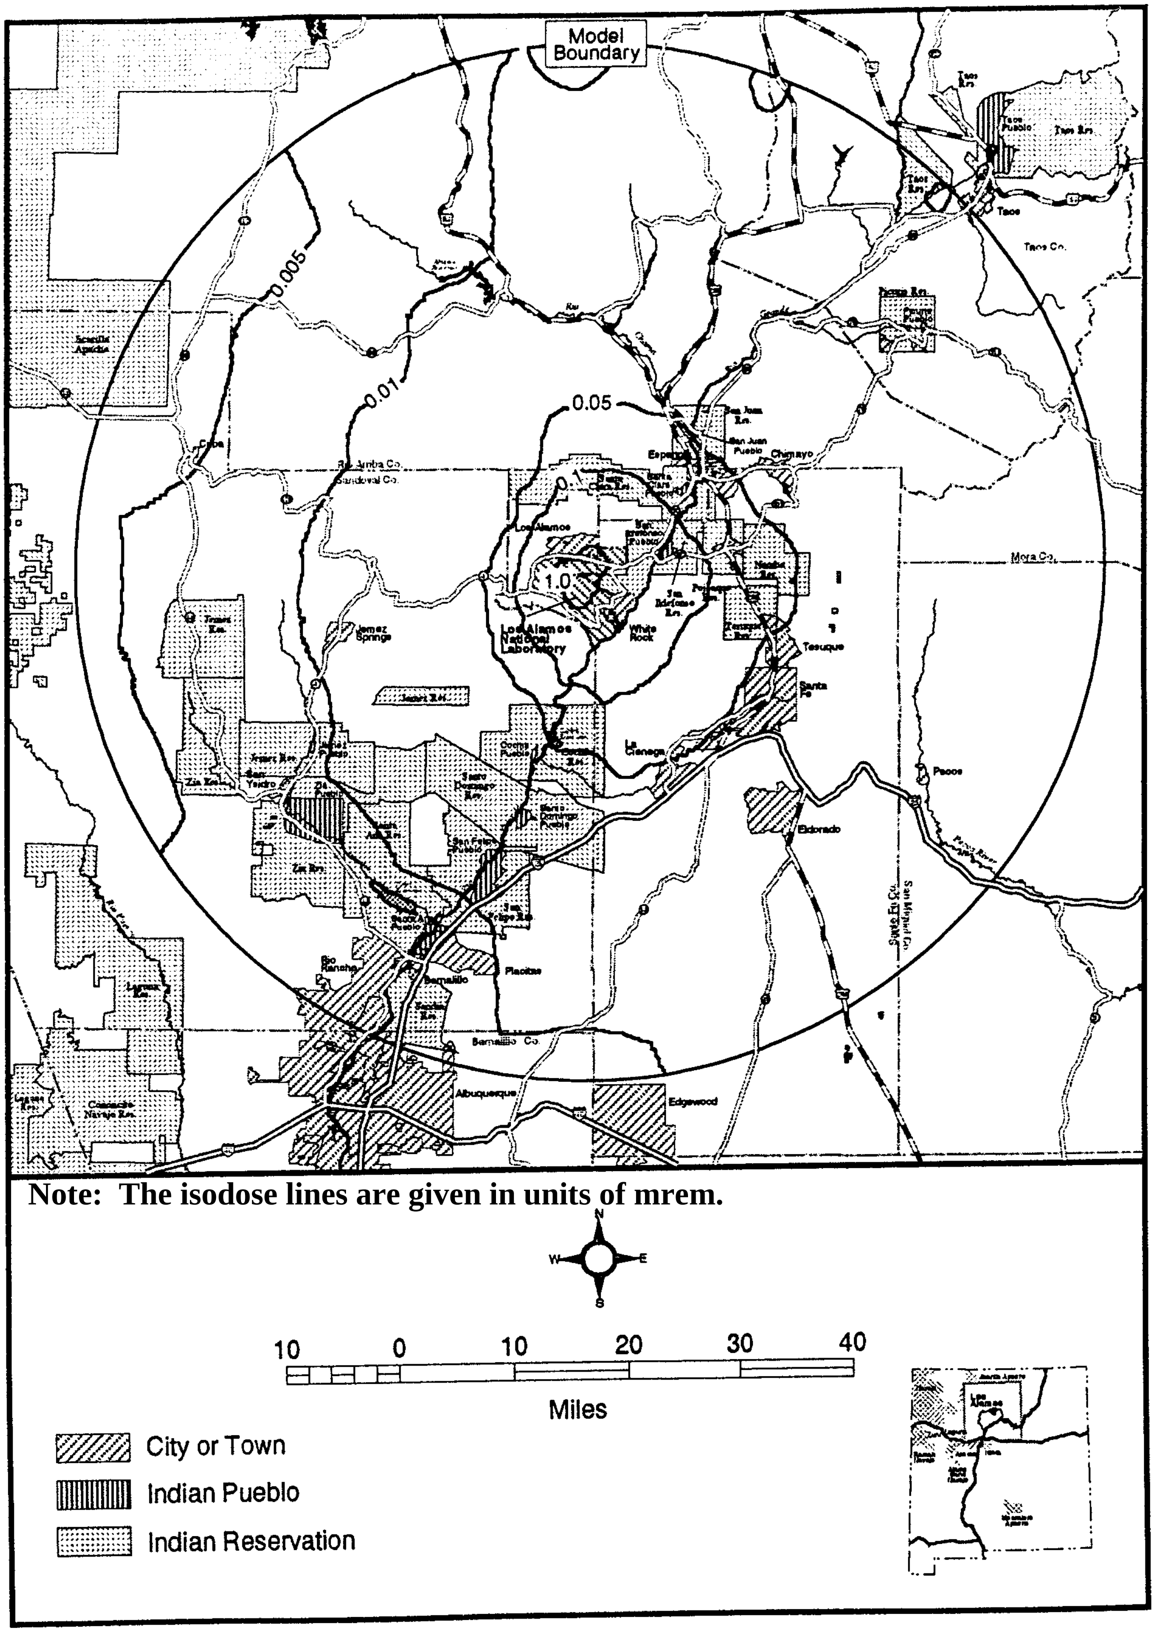

FIGURE 5.5.4.2–2.—***Isodose Map Showing Doses Less Than 1 Millirem per Year for the Greener Alternative.***

TABLE 5.5.6.1–1.—*Estimated Public Health Consequences for LANL MEI and the Population Within 50-Mile (80-Kilometer) Radius of LANL for the Greener Alternative*

PARAMETER	LANL HYPOTHETICAL MEI	50-MILE (80-KILOMETER) RADIUS POPULATION
Dose (Committed Effective Dose Equivalent)	4.52 millirem/year	13.79 person-rem/year
Excess LCF	0.0002/lifetime (72 year)	0.0069/year of operations

under the Greener Alternative from that estimated under the No Action Alternative (an EDE of 2.9 millirem per year and a lifetime excess LCF risk of about 1 x 10^{-6} per year of operation).

The other contribution to public dose, as discussed in section 5.2.6.1, would result from TA–18 "road-open" operations. At the 95 percent confidence level, four exposures per year would be expected for the MEI out of the 100 operations per year at TA–18 under the Greener Alternative (the same as for the No Action Alternative). This would result in an annual projected MEI EDE dose of 19 millirem per year. The lifetime excess LCF risk for this dose is about 9.5 x 10^{-6} per year of operation.

Nonionizing Radiation

The only uncontained nonionizing radiation source in use or planned for LANL is the microwave transmitter in TA–49. The consequence of a public exposure to this source under the Greener Alternative is the same as for the No Action Alternative; as discussed in section 5.2.6.1, this consequence is negligible.

Consequences of Airborne Chemical Emissions

For the Greener Alternative, these consequences are the same as those under the No Action Alternative; the worst case HI for lead did not exceed one in a million (10^{-6}); for DU, the worst case HI did not exceed 1 in 100,000 (0.00010); and the excess LCF for beryllium (evaluated as a carcinogen) under the Greener Alternative was estimated to be less than 3.6 x 10^{-7} per year. These analyses are presented in detail in volume III, appendix D.

Consequences of Ingestion and Dermal Exposures to Residents, Recreational Users, and Special Pathways Receptors

The risk to the public from ingestion under the Greener Alternative does not differ from that associated with the No Action Alternative; this is because most of the risk is attributable to the existing levels of contamination in water and soils in the area. This is discussed further in section 5.2.6.1. Table 5.2.6.1–2 summarizes the ingestion radiological annual dose and excess LCF per year to the MEIs. Tables 5.2.6.1–2 and 5.2.6.1–3 summarize the total radiological annual ingestion dose and excess LCF to members of the public. Per Table 5.2.6.1–3, the total worst-case ingestion doses for the off-site resident of Los Alamos County and non-Los Alamos County resident are 0.011 and 0.017 rem per year, respectively. If this person is also a recreational user of the Los Alamos canyons, drinking canyon water and ingesting canyon sediments, the worst-case additional dose ranges up to 0.001 rem per year, according to the amount of time spent in the canyons (see footnote b in Table 5.2.6.1–3). If the individual has traditional Native American or Hispanic lifestyles, the values found in the final columns of the table should be used in place of the values in the first columns for off-site residents. Per the values in the final columns, these "special pathways receptors" can have worst-case 3.1 millirem per year additional dose. The associated excess LCF risks for the off-site residents are 8.6×10^{-6} per year of exposure and 9.1×10^{-7} per year of exposure for the individual who is also an avid recreational user. These worst-case doses are for a 95th percentile intake of the 95th percentile contamination level, referred to as the UCL. Ingestion pathway calculations included all radionuclides detected in the media. This includes natural background, weapons testing fallout, and previous releases. The actual contribution from continued operations at LANL is only a small fraction of this value. These values apply to the baseline and to all four alternatives. The data and analyses for these calculations are in appendix D, section 3.3. Table 5.2.6.1–3 summarizes the risk associated with metals ingestion to MEIs in the LANL region.

Consequences to the Public along Transportation Routes

Section 5.5.10 details the analysis of transportation consequences. Public health consequences include the dose and excess LCF risk associated with routine, accident-free, transportation. Table 5.5.10–2 shows the population dose and excess LCF for normal (accident-free) off-site shipments. The population dose and excess LCF that are associated with exposures occurring during stops for transportation segments near LANL are provided in Table 5.5.6.1–2. Doses associated with living along route and sharing routes with these shipments are detailed in Table 5.5.10–2, and are less than those associated with stops. Risks associated with accidents during transportation also are discussed in section 5.5.10.

TABLE 5.5.6.1–2.—*Radiation Doses and Excess LCF Risks Estimated to the Public at Stops During Transportation of Materials and Wastes from LANL*

ROUTE SEGMENT	PERSON-REM PER YEAR (AT STOPS)	EXCESS LCF RISK PER YEAR
LANL to U.S. 84/285	3.6	0.0018
U.S. 84/285	3.8	0.0019

5.5.6.2 *Worker Health*

Worker risks associated with continued operations of LANL include radiological (ionizing and nonionizing) risks, chemical exposure risks, and risk of injury during normal operations. The consequences to worker health from implementing the Greener Alternative are given below and detailed in volume III, appendix D, section D.2.2.

Radiological Consequences

Ionizing Radiation Consequences. Table 5.5.6.2–1 summarizes the projected doses and associated excess LCF risks from implementation of the Greener Alternative.

The collective worker dose under the Greener Alternative is conservatively projected to be approximately 2.3 times that measured in 1993 to 1995. In terms of the average non-zero dose, the Greener Alternative is expected to result in

TABLE 5.5.6.2–1.—*Annual Worker Doses and Associated Lifetime Excess LCF Risks Under the Greener Alternative*

LANL Collective Worker Dose (person-rem/year)	472
Estimated Excess LCF Risk (across the worker population) per year of operation	0.19
Average Non-Zero Worker Dose (rem/year)	0.14
Estimated Excess LCF Risk (average worker > 0 dose)	0.000056

0.14 rem per year for Greener, compared with 0.097 rem per year, 1993 to 1995. The estimated lifetime excess LCF risk is 0.000056 per year of operation.

Nonionizing Radiation. It is expected that there will continue to be negligible effects to LANL worker health from nonionizing radiation sources including ultraviolet sources, infrared radiation from instrumentation and welding, lasers, magnetic and electromagnetic fields, and microwaves (including the large station at TA–49). (Also see volume III, appendix D, section D.2.2.2 for evaluation used to estimate nonionizing radiation from LANL operations to humans and wildlife and for the estimated results.)

Carcinogenic Risk from Air Emissions

The screening process described in appendix B identified no individual carcinogenic chemical air emission that required analysis for public health consequences. For carcinogens, an estimate also was made of the combined lifetime incremental cancer risk due to all carcinogenic pollutants from all TAs (appendix B, attachment 6).

This incremental combined cancer risk is less than 1 in 1 million for the Greener Alternative because the projected emissions for this alternative are less than for the Expanded Operations Alternative (which was slightly above the screening guideline value of 1×10^{-6}). It is believed that negligible increase in incremental combined cancer risk will result from the Greener Alternative.

Chemical Exposure Consequences

It is anticipated that there will continue to be a few chemical exposures annually, particularly exposures to:

- Airborne asbestos
- Lead paint particulates
- Crystalline silica
- Fuming perchloric acid, hydrofluoric acid
- Skin contact with acids or alkalis

Under the Greener Alternative, it is expected that there will be a worker population of approximately 10,000 individuals, approximately 10 percent higher than the index period employment levels. For the purposes of the SWEIS, it is assumed that there is negligible additional benefit of the Chemical Hygiene Program at LANL over the period analyzed, and that the rate of chemical exposures continues at the index period rates. Therefore, it is expected that reportable chemical exposures would not change appreciably from the index period, approximately one to three reportable chemical exposures per year.

Beryllium Processing Consequences. It is anticipated that beryllium operations in the Reduced Operations Alternative would be the same as in the No Action Alternative. It is not anticipated that consequences to workers would be measurable; that is, no sensitization to beryllium would be detected using the LANL IH monitoring program.

Physical Safety Hazards

Table 5.5.6.2–2 compares the projected reportable cases of accidents and injuries estimated for normal operations occurring under the Greener Alternative and that experienced during the index period. The Greener Alternative is expected to result in a slight increase in reportable cases due to increases in worker population. These accidents and injuries are considered as consequences of normal operations because of their frequency. These results assume that the aggressive Health and Safety Program underway at LANL does not achieve any additional reduction in reportable cases.

The consequences of these accidents and injuries are expected to be similar to those experienced in the past, and typically are those

TABLE 5.5.6.2–2.—*Projected Reportable Annual Accidents and Injuries for the Greener Alternative Compared with the Index Period*

PARAMETER ESTIMATED	PARAMETER VALUE AND UNITS
Projected Worker Population	Approximately 10,000
Projected Reportable Accidents and Injuries	460/year
Change from Index (1993 to 1996)	+ 10%

associated with health response and recovery from acute trauma. Therefore, the consequences include physical pain and therapy/treatment for recovery such as those associated with bone setting, shoulder dislocation reset and subsequent physical therapy. Some injuries also may result in continuing consequences to the worker that could affect productivity or lifestyle, such as motor skill loss due to nerve damage or cardiovascular debilitation resulting from electrical shock or electrocution.

5.5.7 Environmental Justice

As indicated in sections 5.5.1 and 5.5.2, no substantive adverse impacts to land resources or geology and soils are anticipated for the continued operation of LANL under the Greener Alternative. Thus, no disproportionately high and adverse impacts to minority or low-income communities are anticipated for these impact areas. The potential impacts to surface and groundwater and ecological resources associated with the Greener Alternative would affect all communities in the area equally (see sections 5.5.3 and 5.5.5 for additional information on the potential for impacts to these resources). Thus, no disproportionately high or adverse impacts to minority or low-income communities are anticipated to be associated with these resource areas.

Figure 5.5.7–1 reflects the dose from radiological air emissions within 50 miles (80 kilometers) of LANL under the Greener Alternative. As discussed in section 5.2.7, impacts due to air emissions are equal to or lower in the sectors with substantial minority and/or low-income populations than they are in sectors 1–3 and 6–16, and such impacts are not disproportionately high or adverse with respect to the minority or low-income populations (see section 5.5.4 regarding the impacts anticipated for air emissions under the Expanded Operations Alternative).

The air pathway is one example of the analysis of potential human health impacts. As presented in section 5.5.6, there is minimal potential for LANL operations to adversely affect human health for off-site residents or recreational users in the area around LANL under the Greener Alternative. Similarly, the special pathways have little potential to impact human health under this Alternative. Thus, the Greener Alternative would not present disproportionately high or adverse impacts to human health in minority or low-income communities (section 5.4.6.1).

As shown in section 5.5.10, impacts from on-site transportation and from LANL to U.S. 84/285 are estimated to be 0.0018 excess LCFs per year from incident-free transportation and 0.040 deaths or injuries per year from transportation accidents. Impacts from transportation on route segments that pass through minority or low-income communities (particularly the segment from U.S. 84/285 to I–25) are estimated to be 0.0019 excess LCFs per year from incident-free transportation and 0.091 deaths or injuries per year from transportation accidents. Therefore, no high and adverse impact is expected to either a member of the general public or to a member of a minority or low-income population due to

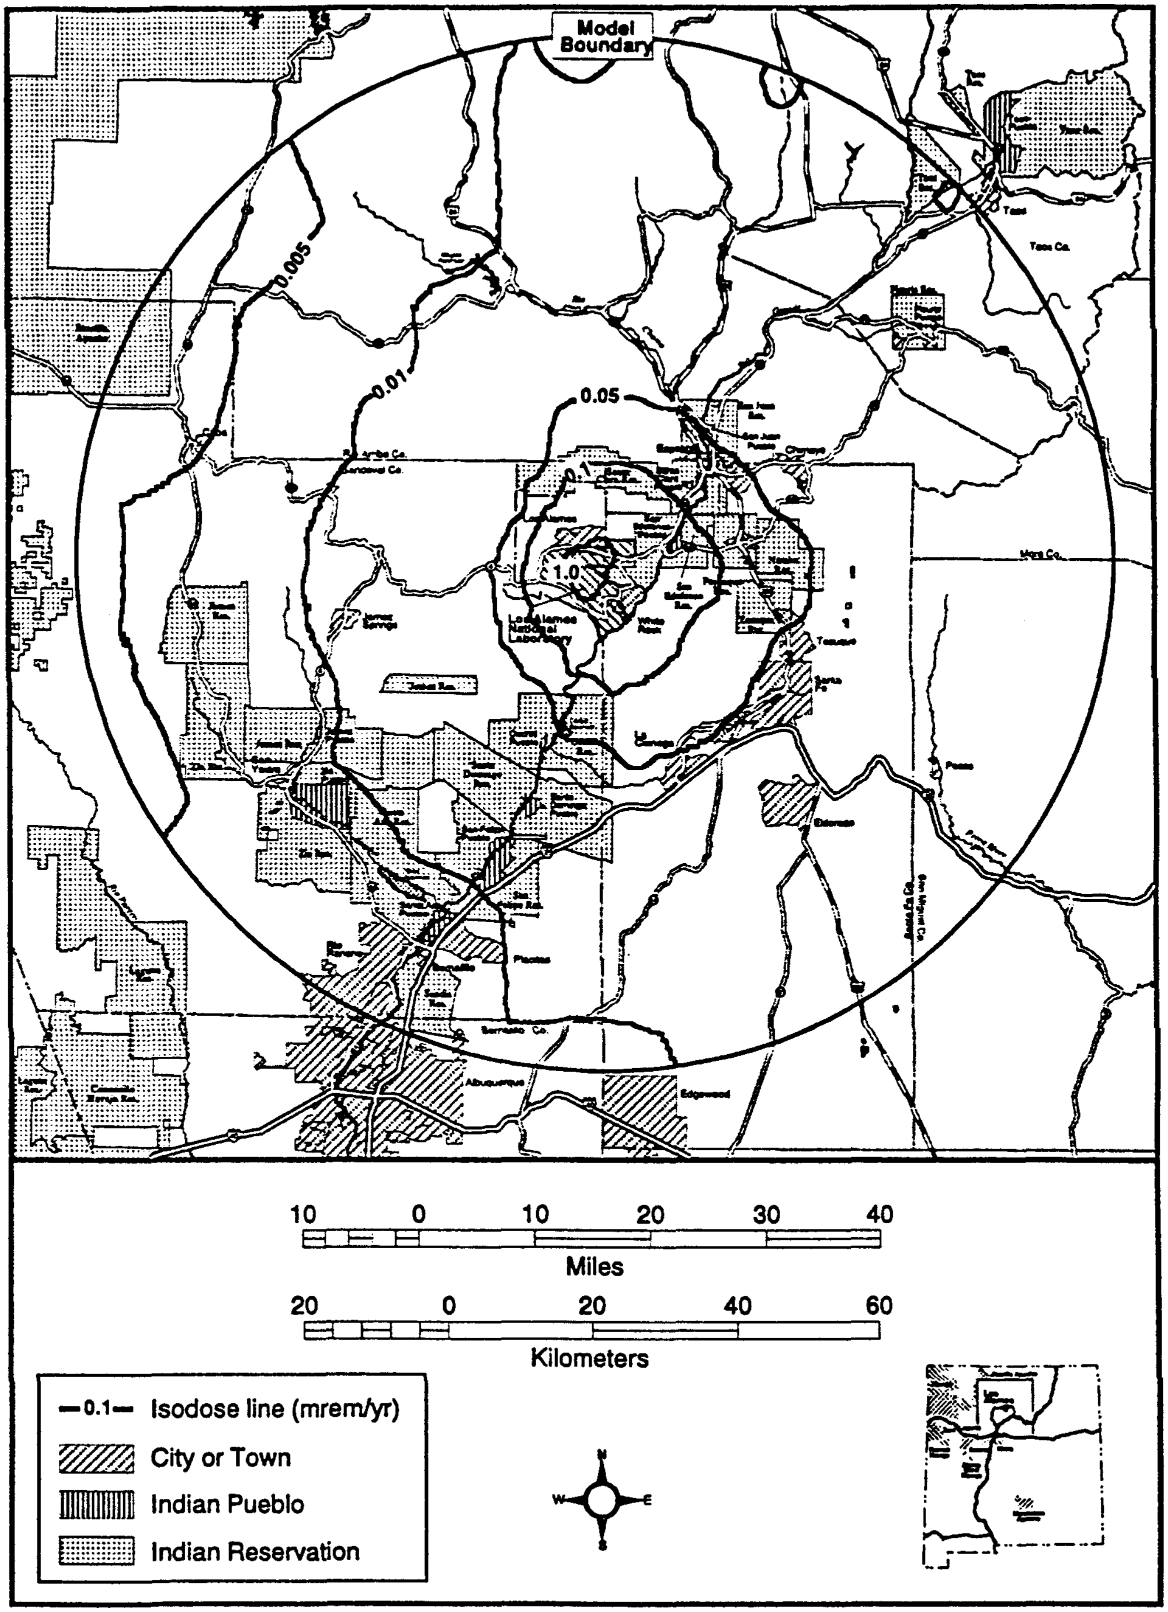

FIGURE 5.5.7–1.—*Isodose Lines from Airborne Releases for the Greener Alternative Within 50 Miles (80 Kilometers) of LANL.*

transportation in the vicinity of LANL transportation routes.

5.5.8 Cultural Resources

Construction activities and explosive test activities under this alternative are essentially the same as those under the No Action alternative. Because these are the activities with the most potential for impacts to cultural resources, impacts to prehistoric resources, historic resources, and TCPs under the Greener Alternative would be similar to those stated for the No Action Alternative in section 5.2.8. Management and protection of prehistoric and historic resources also would be similar to that of the No Action Alternative.

Spiritual Entities

As with the No Action Alternative, no assessment of impacts to "unseen" or "spiritual" entities was attempted.

5.5.9 Socioeconomics, Infrastructure, and Waste Management

This section describes the social, economic, and infrastructure impacts of activities at LANL under the Greener Alternative.

5.5.9.1 *Socioeconomic Impacts*

Employment, Salaries, and Population

The primary (direct) impacts of this type are presented in Table 5.5.9.1–1 for the LANL workforce only. The secondary (indirect) impacts and the total population changes projected are presented in Table 5.5.9.1–2 for the Tri-County area. These changes are assumed to occur within a year of the ROD for the SWEIS.

Housing

The population changes anticipated in the Tri-County area, based on the total employment changes described above, are projected to result in 551 additional (new) demand for housing units. The distribution of this demand in the three counties is projected to be: 130 additional units in Los Alamos County, 197 additional units in Rio Arriba County, and 224 additional units in Santa Fe County.

In Los Alamos County, the projected housing demand can be accommodated from absorption of apartment vacancies and the inventory of houses for sale and new construction. Beyond 130 units, no new housing units can be anticipated because of the absence of buildable land in private ownership. This constraint upon supply would be expected to exert an upward pressure on rents and house prices.

The projected housing demand in Rio Arriba and Santa Fe counties can be accommodated without significant pressure on rents and house sales prices. Both counties possess a sufficient inventory of finished lots and parcels, have access to adequate mortgage capital, and have sufficient entrepreneurial developer talent to absorb the demand.

Construction

Table 5.5.9.1–3 contains the results of the analysis of construction spending, labor salaries, and labor employment for the period fiscal year 1997 through fiscal year 2006. Construction activities associated with this alternative are expected to draw workers already present in the Tri-County area who historically have worked from job to job in the region. Thus, this employment is not expected to influence socioeconomic factors such as local government finance.

Under this alternative, the Tri-County annual gross receipts tax yields would be expected to increase by $1.1 million. This increase would

TABLE 5.5.9.1–1.—*Summary of Primary LANL Employment, Salaries[a], and Procurement Under the Greener Alternative[b]*

	LOS ALAMOS COUNTY	RIO ARRIBA COUNTY	SANTA FE COUNTY	TRI-COUNTY TOTAL	OTHER NEW MEXICO COUNTIES	NEW MEXICO TOTAL	OUTSIDE NEW MEXICO	TOTAL
Employees	4,995	2,082	2,032	9,109	661	9,770	198	9,968
Difference[c]	160	163	195	518	53	571	22	593 (+6%)

be matched by increases in service levels adequate to meet public demand.

Services

Annual school enrollment in the Tri-County area would increase by 224 students. Additional annual funding assistance of about $898,000 from the State of New Mexico would be required for school operations because of these enrollment increases.

In Los Alamos, the school district can absorb the anticipated new enrollment levels. This school district has excess capacity because of its discretionary policy of accepting out-of-district students who are the children of LANL employees and subcontractors. In Rio Arriba County and the cities of Española and Santa Fe, adequate classroom capacity exists because of recent school construction projects.

The demands for police, fire, and other municipal services would be expected to increase in proportion to the increase in gross receipts tax yields, as discussed above. However, any changes in local government services tend to be inelastic in the short term and typically are responsive only after the completion of at least one full budget cycle.

5.5.9.2 *Infrastructure Impacts*

Annual electricity use projected under the Greener Alternative is a total of 782 gigawatt-hours, 437 gigawatt-hours for LANSCE, and 345 gigawatt-hours for the rest of LANL. The peak electrical demand is projected to be 113 megawatts, 63 megawatts for LANSCE and 50 megawatts for the rest of LANL[1]. The existing supply of electricity to the Los Alamos area is not sufficient year-round to meet the projected electrical peak demand for LANL operations under this alternative; thus, periods of brown-outs are anticipated unless measures are taken to increase the supply of electricity to the area. (In chapter 1, sections 1.6.3.1 and 4.9.2 discuss ongoing efforts to increase electrical power supply to this area.) This situation is exacerbated by the additional electrical demand for BNM, and the communities of Los Alamos and White Rock. (While these organizations did not provide use projections, their historical usage is reflected in chapter 4, section 4.9.2.)

Natural gas use is projected to be 1.84×10^6 decatherms annually, the same as projected under the No Action Alternative. Although electrical demand may increase natural gas demand for the generation of electricity at TA–3, demand should continue to be dominated by heating requirements and is not expected to exceed this projection.

Water use projected under the Greener Alternative is a total of 759 million gallons

1. These values include the proposed SCC Project annual electricity and peak electrical demand for a 50-TeraOp operation and are reflected in all the alternatives. The SCC project was as an interim action to the SWEIS.

(2,873 million liters) per year, 265 million gallons (1,003 million liters) per year for LANSCE and 494 million gallons (1,869 million liters) per year for the rest of LANL. This is well within DOE water rights, about 1,806 million gallons (6,836 million liters) per year; however, this water right also provides for water used by Los Alamos County and BNM. Based on existing information regarding non-LANL water use, the water demands of this community can be met within the existing water rights (water demand is also discussed in section 5.5.3). The peak water requirements are the same as identified under the No Action Alternative.

5.5.9.3 *Waste Management*

The annual and 10-year total generation projections for radioactive and hazardous waste are reflected in Table 5.5.9.3–1. Radioactive liquid is not projected by facility because measurements of individual contributions are not made for all facilities. The total amount of radioactive liquid waste projected for receipt at TA–50 is 66 million gallons (250 million liters) over 10 years (or an average of 6.6 million gallons [25 million liters] per year) for this alternative. These projections include waste from key facilities, all other LANL facilities, waste management facilities, the ER Project, and construction activities.

The waste volumes generated under this alternative are very similar to those under the No Action Alternative; TRU and mixed TRU wastes under this alternative are lower (due to the reduced weapon-related activities), while the other categories are slightly higher (due to the increased nonweapons work). As with the No Action Alternative, much of LANL’s LLW, TRU, and chemical waste would be treated and packaged to meet WAC and shipped off the site for disposal; nondefense TRU waste from other sites would be stored at LANL pending the development of disposal options. Off-site disposal capabilities are much greater than the waste volumes generated at LANL.

5.5.9.4 *Contaminated Space*

The activities reflected in the Greener Alternative are projected to increase the total contaminated space at LANL by 63,000 square feet (5,853 square meters) over the next 10 years (the same as for the No Action Alternative), as compared to the baseline established for the SWEIS as of May 1996 (chapter 4, section 4.9). The majority of this increase is due to implementation of actions that have already been reviewed under NEPA, but which had not been implemented at the time the baseline was established (the same ones discussed in the No Action Alternative).

5.5.10 Transportation

5.5.10.1 *Vehicle-Related Risks*

The transportation impacts projected for the Greener Alternative are summarized in this section. As with the Reduced Operations Alternative, most of the LLW generated is shipped off the site for disposal under the Greener Alternative. While most other shipments are similar to those under the No Action Alternative, these LLW shipments increase the total number of shipments and total shipment miles enough that the transportation impacts under the Greener Alternative approach (but are less than) those of Expanded Operations for off-site radioactive material shipments. More detailed information regarding these impacts is included in volume III, appendix F.

Truck Emissions in Urban Areas

For the Greener Alternative, the projected risk is 0.036 excess LCF per year. Use of the Santa Fe Relief Route would have a very small effect on this risk (it would change to 0.035 excess LCF per year). The only difference is that the Santa Fe Relief Route would have 1.2 miles (1.93 kilometers) less of urban highway mileage. Approximately 65 percent of the excess LCFs are due to radioactive material

TABLE 5.5.9.3–1.—*Projected Annual and 10-Year Total Waste Generation Under the Greener Alternative*[a]-Continued

NA indicates that this facility does not routinely generate these types of waste.

[a] Radioactive liquid waste generation is not projected by facility (see text in section 5.5.9.3, Radioactive and Hazardous Waste Generation).

[b] The chemical waste numbers reflect waste that exhibits a hazardous characteristic (ignitability, corrosivity, reactivity, or toxicity), is listed as a hazardous waste by EPA, is a mixture of listed hazardous waste and solid waste, or is a secondary waste associated with the treatment, storage, or disposal of a hazardous waste. This includes waste that is subject to regulation under RCRA, as well as PCB waste and asbestos waste regulated under *Toxic Substance Control Act*. This category also includes biomedical waste.

[c] These projections include 141,000 cubic feet (4,000 cubic meters) of LLW due to backlogged waste.

[d] These LLW projections include 141,000 cubic feet (4,000 cubic meters) of LLW generation anticipated due to the CMR Building Upgrades, Phase II.

[e] These projections include 228,000 cubic feet (6,450 cubic meters) of LLW due to the construction of the new Long-Pulse Spallation Source Facility and 86,000 cubic feet (2,450 cubic meters) of LLW due to upgrades to Areas A5 and A6, as well as reduced operational waste generation during these construction activities.

[f] These projections include 22,000 pounds (10,000 kilograms) of chemical waste, 550 pounds (250 kilograms) of biomedical waste (a special form of chemical waste), 1,560 cubic feet (44 cubic meters) of LLW, and 850 cubic feet (24 cubic meters) of LLMW associated with ongoing efforts to remove obsolete and contaminated equipment.

[g] These facilities provide for storage, treatment, and disposal of waste generated throughout LANL. These activities generate secondary waste, the quantities of which are reflected in this table for these facilities.

[h] The ER Project is projected to generate 390 cubic feet (11 cubic meters) per year of TRU and mixed TRU waste together. All of this waste is presented under the TRU waste columns.

[i] Grand totals have been rounded.

shipments and 35 percent are due to hazardous chemical shipments. All shipments are conservatively assumed to result in an empty truck making the return trip. This is appropriate for WIPP and LLW shipments and for many SST shipments; however, most shipments are in general commerce and would not include the return of an empty truck.

Truck Accident Injuries and Fatalities

The impacts projected for the Greener Alternative are presented in Table 5.5.10.1–1 (additional information is provided in volume III, appendix F, section F.6.3). Use of the Santa Fe Relief Route would reduce the risks of accidents, injuries, and fatalities by almost one-half of those indicated for the segment from U.S. 84/285 to I–25 due to the assumption that the accident rate on the Santa Fe Relief Route would be much lower than for the route through Santa Fe. Use of the Santa Fe Relief Route would not substantially change the risks of accidents, injuries, and fatalities on the remainder of New Mexico segment, as compared to the risks reflected for this segment in Table 5.5.10.1–1. Approximately 65 percent of the impacts are due to radioactive material shipments and 35 percent are due to hazardous chemical shipments. Again, all shipments are assumed to result in a return by an empty truck.

5.5.10.2 *Cargo-Related Risks*

Incident-Free Radiation Exposure

The incident-free radiation exposure impacts projected for the off-site shipments under the Greener Alternative are presented in Table 5.5.10.2–1; as noted in section 5.2.10.2, the total is the dose throughout the U.S. and is dominated by the segments outside of New Mexico. The aircraft segment is for overnight carrier service; the truck segment to and from the airport is included in the truck results. In general, use of the Santa Fe Relief Route would result in only small changes in this type of impact. Truck crew doses and nonoccupational doses for people at rest stops would increase due to the increased length of the Santa Fe Relief Route for north-bound shipments carrying the radioactive material. Nonoccupational doses for people sharing the road would decrease due to the lower traffic density projected for the relief route. The MEI dose occurs between LANL and I–25 and is 0.00034 rem.

Driver Doses from On-Site Shipments of Radioactive Materials

The projected collective radiation dose for on-site shipments of radioactive materials is 4.5 person-rem. This collective dose would be expected to result in 0.00181 excess LCFs among these drivers.

The average individual driver dose is projected to be 0.189 rem, which is well below the DOE radiation protection limit of 5 rem per year.

Transportation Accidents

The following discussion addresses the potential impacts of accidents leading to the release of either radioactive or hazardous material being transported in support of LANL operations under the Greener Alternative. Results are given for both off-site and on-site shipments.

Off-Site Radioactive Materials Shipments. The MEI doses calculated with RADTRAN do not vary by alternative and are given in Table 5.2.10.2–2. The population dose and corresponding excess LCF per year for these shipments are presented in Table 5.5.10.2–2 for these accidents. ADROIT results that are separated into frequency and consequence components are not readily available. The product, MEI dose risk, can be presented in terms of excess LCF per year; for the Greener Alternative, the MEI dose risk due to plutonium-238 oxide and due to pit shipments were each less than 1×10^{-10} excess LCF per year.

TABLE 5.5.10.1–1.—*Truck Accident Injuries and Fatalities Projected for LANL Shipments Under the Greener Alternative*

ROUTE SEGMENT	NUMBER OF ACCIDENTS PER YEAR	NUMBER OF INJURIES PER YEAR	NUMBER OF FATALITIES PER YEAR

LANL to U.S. 84/285	0.016	0.0015	3.2×10^{-6}	4×10^{-7}	2×10^{-6}	0.018	9.0×10^{-6}
U.S. 84/285 to I–25	0.25	0.02	0.000044	1×10^{-6}	8×10^{-6}	0.27	0.00014
Remainder of New Mexico	0.033	0.013	0.000027	4×10^{-7}	4×10^{-6}	0.046	0.000023
Rest of U.S.	2.7	NA	NA	4×10^{-6}	0.00001	2.7	0.0014

NA = Not available; CH TRU = contact-handled TRU waste; RH TRU = remote-handled TRU waste

The use of the Santa Fe Relief Route would reduce the projected population dose (and therefore, the excess LCFs per year) by about one-third for the U.S. 84/285 to I–25 segment, as compared to use of the route through Santa Fe. This difference is primarily due to the difference in population density along these routes. (The lower traffic density along the relief route is also a factor.) The use of the Santa Fe Relief Route would increase the projected population dose (and therefore the excess LCFs per year) for the remainder of New Mexico segment to about double that identified if the route through Santa Fe is used. This difference is due to the increase (6 miles [9.65 kilometers] more) in the distance traveled on I–25 for north-bound shipments.

On-Site Radioactive Materials Shipments. The MEI doses, frequencies, and MEI risks due to the bounding on-site shipments involving radioactive materials are given in Table 5.5.10.2–3. As noted in section 5.2.10.2, the frequency of the bounding DARHT and PHERMEX shipments has been added to the frequency of irradiated target shipments.

Hazardous Materials Shipments. The bounding hazardous materials shipments for accident analyses are major chlorine shipments (toxic), major propane shipments (flammable), and major explosive shipments. The consequences of an accident involving a major explosive shipment is bounded by the consequences of an accident involving a major propane shipment, so the frequency of

TABLE 5.5.10.2–3.—*MEI Doses and Frequencies for Bounding On-Site Radioactive Materials Accidents Under the Greener Alternative*

SHIPMENT TYPE	EVENT FREQUENCY PER YEAR	MEI DOSE	MEI RISK
Plutonium-238 Solution	8.8×10^{-8}	8.7 rem	7.7×10^{-7} rem/year (3.1×10^{-10} excess LCF/year)
Irradiated Targets	3.2×10^{-6}	acute fatality	3.2×10^{-6} fatalities/year

explosives shipments was added to the frequency of propane shipments (rather than analyzing them separately).

Accidental Chlorine Release. The projected frequencies, consequences, and risks associated with major chlorine accidents under the Greener Alternative are presented in Table 5.5.10.2–4.

The use of the Santa Fe Relief Route would result in about one-sixth the risk of fatalities and one-tenth the risk of injuries on the U.S. 84/285 to I–25 segment, as compared to the use of the route through Santa Fe. These differences are due to the lower population density along the Santa Fe Relief Route. The use of the Santa Fe Relief Route would result in a slight increase in injuries and fatalities on the remainder of New Mexico segment because of the extra 6 miles (9.65 kilometers) traveled on I–25 for northbound traffic (chlorine shipments are all assumed to travel north on I–25).

Accidental Propane Release. The projected frequencies, consequences, and risks associated with major propane accidents under the Greener Alternative are presented in Table 5.5.10.2–5.

The use of the Santa Fe Relief Route would result in about one-third the risk of fatalities and one-fourth the risk of injuries on the U.S. 84/285 to I–25 segment, as compared to the use of the route through Santa Fe. These differences are due to the lower population density along the Santa Fe Relief Route. The use of the Santa Fe Relief Route would result in a slight decrease in injuries and fatalities on the remainder of New Mexico segment because of the 6 miles (9.5 kilometers) reduction in distance traveled on I–25 for southbound traffic (propane shipments are all assumed to travel south on I–25).

5.5.11 Accident Analysis

Transportation accidents for the Greener Alternative are addressed in section 5.5.10. High-frequency (greater than 1 in 100) occupational accidents for the Greener Alternative are addressed in section 5.5.6.

5.5.11.1 *Multiple Source Release of Hazardous Material from Site-Wide Earthquake and Wildfire*

The risks from these accidents are driven primarily by the frequency and magnitude of an earthquake and wildfire in the area. Because the same types of operations will be conducted in the same facilities and the inventories of MAR will be about the same, there are no substantial changes between the No Action and the Greener Alternatives. Tables 5.2.11.1–1 and 5.2.11.1–2 show these results.

5.5.11.2 *Plutonium Releases from Manmade and Process Hazards at LANL*

For the Greener Alternative, the activities and conditions that determine the material release and accident progressions do not change. Therefore, the frequencies and consequences of these scenarios under the Greener Alternative are the same as those presented for the No Action Alternative in Table 5.2.11.2–1.

An overview of the 1969 plutonium fire at the Rocky Flats site and a comparison of the design and operational differences between the Rocky Flats Plant and TA–55–4 are presented in volume III, appendix G, section G.4.1.2.

Substantial differences exist between the nuclear facility and operations being conducted at TA–55–4 today and those that were present at the Rocky Flats Plant in 1969. TA–55–4 was designed to correct the deficiencies detected in older facilities such as the Rocky Flats Plant and is being upgraded to meet the even more stringent requirements of the 1990's, including

	Urban	5.3×10^{-6}	1.9	7.5		

[a] Because individual factors were rounded for presentation, multiplication of the factors on this table may not exactly match the results in these columns.

enhanced seismic resistance and fire containment.

5.5.11.3 *Highly Enriched Uranium Release from Process Hazard Accident at LANL*

As discussed in section 5.2.11.3, this accident is the dominant accident for the release of HEU. Because there are no planned changes in the number of experiments or the inventories associated with this activity, the frequency and consequences of this scenario under the Greener Alternative are the same as presented under the No Action Alternative in Table 5.2.11.3–1.

5.5.11.4 *Tritium Release from a Manmade Hazard*

As presented in section 5.2.11.4, the aircraft crash event is the dominant accident that involves tritium. Because no changes in operations or inventories from the No Action Alternative are made, the consequences and frequencies associated with these scenarios are the same as those presented for the No Action Alternative in Table 5.2.11.4–1.

5.5.11.5 *Chemical Releases from Manmade and Process Hazard Accidents at LANL*

For the chlorine releases, on-site personnel could be exposed to concentrations in excess of ERPG–2. Chlorine has a highly objectionable odor, which prompts sheltering and escape; however, personnel can be quickly overcome when exposed to high concentrations.

Because no changes in operations or inventories from the No Action Alternative are made, the frequencies and consequences of these scenarios are the same as those under the No Action Alternative, as presented in Tables 5.2.11.5–1 and 5.2.11.5–2.

5.5.11.6 *Worker Accidents at LANL*

Although there are some planned decreases under this alternative in the handling of high explosives, the accident frequencies remain within same range of values as for the No Action Alternative. Therefore, the frequencies and consequences of these scenarios under the Greener Alternative are the same as those presented for the No Action Alternative in Table 5.2.11.6–1.

5.6 CUMULATIVE AND UNAVOIDABLE IMPACTS

5.6.1 Cumulative Impacts

Cumulative impact is defined by the CEQ NEPA regulations as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of which agency (federal or not federal) or person undertakes such other actions." This discussion of cumulative impacts deals with the effect of LANL operations when added to similar effects from the actions of other entities within the same region of influence. Effects are discussed by impact or resource area, and as can be seen from the discussions of each environmental impact area of analysis in chapter 5, the region of influence can vary. Some effects of LANL operations are not detectable beyond the facility or site boundary, while others involve effects with the potential to extend beyond site boundaries, interact with other sources of the same impact, and so may be managed under a regional regulatory authority (such as for criteria pollutants under the *Clean Air Act)*. Other effects, such as fire control or the movement of grazing animals, are best viewed within a common habitat or natural resource area.

This site-wide analysis in large measure is, by its scope, an analysis of cumulative impacts. To analyze the effects of LANL operations, regions of influence were selected to identify the maximum extent of impacts while still providing a discussion of effects that can be evaluated meaningfully. These impacts represent the effects from all operations at the site, and some effects do not have contributors from sources other than LANL. The following discussion represents all operational alternatives. The nature of the impacts from LANL operations and those of the surrounding area are such that the analyses presented in the previous sections of chapter 5 are, in fact, most of the relevant materials on this subject. The discussion that follows is not greatly influenced by the variation in impacts from the alternatives because most of these impacts are not significant and/or there is little contribution to impacts from other sources that are in the same region of influence as LANL. Information was gathered from city, county, state, tribal, and other federal organizations concerning future plans for development and to get information on any regional planning efforts. Following is a summary of the effects from LANL operations presented in this regional context and in a cumulative sense where such additional information was not already used in the previous section of the impact analysis.

5.6.1.1 *Land Use*

Much of the area around LANL is undeveloped USFS and NPS land, and is projected to remain undeveloped. Future land use patterns are projected to remain the same within the LANL site, and trends in population growth for the region immediately surrounding Los Alamos are likely to continue to increase the urban nature of development. Sections on land use in chapters 4 and 5 of this document provide more detail on these subjects and the cumulative impacts for this aspect of the analysis.

There is a potential for a change in these projections in land use for some parcels on the LANL site that have been identified for possible conveyance and transfer as part of PL 105-119 (also see chapter 4, section 4.1.1.4). The DOE has submitted the first required deliverable to Congress that gives a preliminary identification of 10 parcels that could be considered for transfer, comprising a total of approximately 4,600 acres (1,860 hectares). Those parcels are being evaluated further in the LANL Conveyance and Transfer (CT) EIS (DOE 1998a) (see chapter 1, section 1.5.10) for possible restrictions that may limit their use because of cultural and ecological resource impacts. These parcels also will be evaluated by the ER Project to determine whether any needed remedial actions to allow unrestricted use are practical and could be completed in a 10-year time frame. Transferred lands are available for historic, cultural, or environmental preservation purposes; economic diversification purposes; or community self-sufficiency purposes, as stated in the law. A maximum of 1,158 acres (468 hectares) of the total acreage proposed to be transferred and conveyed would be developed or the land use otherwise changed (DOE 1998a).

5.6.1.2 *Water Resources*

Direct wastewater discharges to the canyons were evaluated in previous sections of this chapter, and no impacts were identified from the quality of current discharges. Soil contaminants from past operations can be affected by surface water flows within the canyons and potentially be carried further down the canyons and into the perched water zones or the underlying deep aquifer. The potential for this type of transport from stormwater runoff as well as transport caused by potential variation in future industrial discharges are discussed in this document. These also are factors in mitigative actions and specific risk analyses for each of the units to be evaluated under the ER Project. No other major water discharge to upper and middle reaches of these canyons occurs from human activity other than from LANL operations and the sanitary wastewater treatment that is performed for these operations as well as for the county, and no other planned discharges were evident. The Los Alamos County sewage treatment plant that discharges into the lower portions of Cañada del Buey is not likely to be a factor of concern for contaminant transport because no contamination above regional background reference levels is found in sediments in that portion of Cañada del Buey or in the lower portion of Mortandad Canyon, which receives the waters from Cañada del Buey. LANL operations are therefore the only activities of interest from the standpoint of cumulative impacts. The Los Alamos County sewage treatment plant in Bayo Canyon does discharge into an area of measurable radioactive contamination from past operations. Levels of contaminants have remained relatively constant in recent years and are slightly above background levels in the vicinity of the plan. While stormwater events are the primary force for movement of sediments, there is the potential for this discharge to contribute to the movement of sediments contaminated with radionuclides in the lower portions of Pueblo Canyon and Los Alamos Canyon. More details on these subjects may be found in the water resource sections of this document.

New development under the CT EIS (DOE 1998a) proposed action could degrade the surface water quality, increasing the pollutant loads and surface runoff volumes from construction activity and the increase in impermeable areas. Increases in discharges to wastewater treatment plants could be 132 million gallons (500 million liters) per year for the Bayo plant and 41 million gallons (155 million liters) per year for the White Rock plant.

5.6.1.3 *Air Quality*

No sources of air pollutants, other than those from LANL operations, were identified that would be of relevance for an evaluation of cumulative impacts; therefore, to give perspective on this situation, a brief description is provided below of the region that could be influenced by LANL operations. Except for Bernalillo County (greater Albuquerque area), the State of New Mexico manages the entire state as one air quality district. This district includes several wilderness areas, national parks, and national monuments and must consider the special status of these areas under the regulations for the prevention of significant deterioration (PSD). The proximity of BNM's wilderness area to LANL is of special note. The largest sources in the state for criteria pollutants are in the Four Corners area, about 200 miles (320 kilometers) to the northwest, and the Bernalillo County area about 50 miles (80 kilometers) to the southwest; but neither areas exhibit major influence in the proximity of the LANL site. Sources in the immediate area are relatively small and separated from one another. Past ambient air quality monitoring by LANL and the State of New Mexico in the vicinity of BNM showed values well below standards developed to protect human health with an ample margin of safety, and monitoring was discontinued in 1994. No future development at LANL is proposed that would require evaluation under PSD regulations. Industrial development in the general area puts little pressure on ambient air quality concerns, and complex permitting or monitoring strategies are not necessary in this area to prevent degradation of air quality.

Only very minor effects from LANL operations could be identified from emissions of toxic air pollutants. No other sources of pollutants having the same potential effect at these receptors of concern for LANL operations were identified. Although some of the impact analyses considered receptors within a 50-mile (80-kilometer) radius of the site, impacts are primarily associated with areas close to the site.

There would be increases in criteria pollutants from mobile sources and homes using natural gas or propane from implementing the CT EIS proposed action. Slight increases in emissions of hazardous air pollutants would be expected from the development of new industrial facilities.

Implementation of the draft Surplus Plutonium Disposition (SPD) EIS Lead Assembly Alternative (DOE 1998b) at LANL would increase the radiological emissions to the MEI by no more than 0.01 millirem per year. Overall, LANL would be expected to remain within the 10 millirem per year NESHAP limit.

5.6.1.4 *Ecological Resources*

The analysis of direct effects on ecological resources from LANL operations in previous sections of this chapter shows that these effects do not, in most cases, extend beyond the perimeter of the site. Where contaminants from LANL are found off the site, contributions from sources other than worldwide fallout were not identified. Analysis of these effects are found in previous sections of this chapter. Additionally, potential effects on biota and ecosystems discussed in those sections are presented within the context of the larger regional ecosystem in which the LANL site is immersed. Potential effects from existing soil contaminants were identified, some dominated by naturally occurring metals, some dominated by legacy contamination from LANL operations. No current or planned additions of contaminants of concern by LANL or any other entity were identified.

The LANL site is relatively large and undeveloped, and serves as a reservation for a wide diversity of plants and animals. Although the impacts to biota and ecosystems are beneficial in this aspect, the site is affected by land uses predating LANL and influenced by fragmented management strategies. Resolution of problems such as risk of catastrophic wildfire, erosion, elk overpopulation, and habitat loss and fragmentation, will benefit from permanent interagency coordination and the development of a joint planning and management program with the other land management agencies. The continuation of and implementation of ongoing site programs and planning actions such as the ER Project, the Threatened and Endangered Species Habitat Management Plan, and the Natural Resources Management Plan will place site managers in a position to contribute in a meaningful way to regionalized strategies as they develop. Discussions in previous sections of this chapter present this regional context in the evaluation of impacts.

Implementation of the CT EIS proposed action would cause approximately 1,230 acres (498 hectares) of ponderosa pine forest and pinyon-juniper woodland habitat to be heavily modified or lost. Also, approximately 3.8 percent of American peregrine falcon and Mexican spotted owl preferred habitat available at DOE/LANL would be affected.

5.6.1.5 *Cultural Resources*

The presence of federal lands adjacent to LANL and the highly restricted nature of the LANL site tends to prevent impacts to these resources from activities other than those directly attributable to LANL operations, and therefore, the discussion of impacts in previous sections of the chapter represents the analysis of cumulative impacts for this aspect of the analysis. Impacts from LANL operations extending beyond the site boundaries were not noted. The analysis in previous sections noted the potential for on-site impacts to TCPs from explosives, residual contamination, and restriction of access; but insufficient information on locations of these sites limits this area of analysis. More information may be found in chapter 4, (section 4.8), chapter 5, and appendix E.

The proposed action under the CT EIS would cause the development of approximately 1,020 acres (413 hectares) and use of tracts for recreation that could result in physical destruction, damage, or alteration of cultural resources on the subject tracts and in adjacent areas.

5.6.1.6 *Socioeconomics*

Government operations (federal, state, local, tribal) and service-sector businesses dominate the economics of the region influenced by LANL by a very large margin. Activities at LANL itself are estimated to directly and indirectly account for more than a third of employment, wage and salary, and business activity in the Tri-County region. The service sector aspect of the economy has experienced little growth in recent years, although projections of population growth, particularly in Santa Fe County, can reasonably be expected to result in the continued major influence of this economic sector. No major fluctuation in other aspects of the economy or introductions of significant new activities were identified. The discussion of impacts in previous sections of this chapter evaluates impacts in the area influenced by LANL (the Tri-County region) and in the context of identified growth patterns. Those sections may therefore be referred to for details on cumulative impacts for this aspect of the analysis.

Short-term economic gains would be expected from employment due to construction activities for new development under the CT EIS proposed action. The long-term gains would be dependent on the intensity and success of the development.

5.6.1.7 *Infrastructure*

LANL is a significant user of electric power in the region, but is not the dominant user in northern New Mexico. Within the electric power pool that serves LANL, direct use by LANL is about 80 percent of the total. The system serving LANL is near capacity, and future projections on electric power use from LANL under all alternatives, except Reduced Operations, indicate that demand will exceed capacity. Consideration of options to increase system capacity is complicated by the fact that the systems for other major power users in the region (the cities in northern New Mexico) are also nearing capacity, and demand from these users is also projected to exceed capacity. While the regional system capacity problem will exist regardless of the alternative selected for LANL operations, selection of an option to deal with LANL alone is strongly influenced by these regional considerations. No specific proposals have been fully developed to remedy this situation (although, as noted in chapter 1, section 1.6.3.1, some specific solutions are being evaluated), and further analysis of environmental impacts will be necessary as future options are developed sufficiently to analyze them. Previous sections of this chapter discuss these electric power issues in the context of regional problems and may therefore be referred to for details on cumulative impacts for this aspect of the analysis.

Natural gas use is projected to remain within the capacity of the current system to provide it. Even if electricity demand increases natural gas demand for the generation of electricity at the LANL main power plant, demand for natural gas should continue to be dominated by heating requirements, and increase in demand sufficient to exceed capacity is not expected. Currently, there are no projections from other consumers in the region using the same natural gas supply lines that show demand potentially exceeding capacity. The evaluation of impacts in this resource area in previous sections of this chapter discuss natural gas use in this regional user context, and may therefore be referred to for details on this aspect of the cumulative impact analysis.

Potable water use was analyzed in previous sections of this chapter in the context of multiple users of a common aquifer and projected future use patterns of these users. The potential drawdown associated with LANL activities as well as services provided to other entities under the DOE water rights were modeled along with the other users in the region. All the users of the aquifer in the Española Basin are assumed to influence one another, but the exact relationships are unknown. Effects such as reduction in the height of the water table at a particular location are primarily influenced by major pumping operations in the immediate area. As pumping by DOE or by the City of Santa Fe shifts from one well field to another, water table height increases in the abandoned area and reduces in the new area. Therefore, even though Santa Fe may be the major water user in the area, total water use in the region still comprises a small fraction of the total volume within the main aquifer, and overall effects, while measurable, are not pronounced. Water use is projected to remain within existing water rights (which cumulatively constitute less than 1 percent of the estimated volume of the aquifer, as discussed in volume III, appendix A, section A.5), and no reduction in the discharge volume from springs in the area is foreseen.

The only aspects of solid waste management that have considerations of cumulative impact are those associated with the multiple users of the Los Alamos County landfill, and the potential for use of the LANL LLW disposal area by other DOE generators. Sufficient capacity in the county solid waste landfill will remain for the foreseeable future, and a decision on expansion of the LLW disposal area is likely to be driven by needs at LANL and not elsewhere. Sections of this document dealing with waste management activities contain more information on this aspect of cumulative impacts.

The total increases in utility usage for the CT EIS proposed action would be as follows:

- Electric use, 31 gigawatt-hours
- Peak power, 5 megawatts
- Natural Gas, 459 million cubic feet
- Water, 382 million gallons per year
- Solid Waste, 2,385 tons per year

Land development under the proposed CT EIS could result in an increased use of 382 million gallons (1,450 million liters) per year of groundwater, a significant increase over the water rights allocation of 1,805 million gallons (6,830 million liters) per year. Under the Expanded Operations and Preferred

Alternatives, the estimated water rights use would be 1,724 million gallons (6,525 million liters) per year. Implementation of the CT EIS proposed action would exceed the water rights allocation. Implementation of the Special Neutron Source (SNS) EIS proposed action of the 1-megawatt beam would use 42 million gallons (160 million liters) per year of groundwater, which could not be met with the current water infrastructure and water rights.

The Spallation Neutron Source (SNS) EIS proposed 1-megawatt beam would use 62 megawatts of peak power. LANL's existing electrical infrastructure is not adequate to support the additional power demand. The increase in peak power demand would exacerbate the power supply-demand problems in the Los Alamos region.

The additional impacts from implementing the draft SPD EIS, Lead Assembly Alternative at LANL would include a total of 4,840 cubic feet (137 cubic meters) of TRU waste, 24,900 cubic feet (705 cubic meters) of LLW, and relatively small quantities of other hazardous and nonhazardous wastes. These impacts are not a significant contributor to the waste management activities at LANL. The annual electricity requirements would increase by 0.72 gigawatt-hours, with an increase peak power demand of 0.3 megawatts. The annual process water usage would increase by 20,000 gallons (76,000 liters) per year. Both the electrical power and water usages are minor in the context of LANL's overall requirements and, thus, are not significant contributors to the power and water concerns at LANL.

5.6.1.8 *Transportation*

The future population of Los Alamos is not projected to increase significantly, although future land transfers may increase local traffic. As discussed in other sections, no other major cause for growth in the region has been identified, although some communities are expected to increase in size just as other areas of the state. Impacts associated with traffic congestion and vehicle emissions discussed in previous sections of this chapter consider the effects attributable to LANL operations in the context of effects that may be present from other sources, as well as the effect of future growth in the area. More detail on cumulative impacts may be found in those sections. Hazardous chemical and radioactive materials shipments comprise about 1 percent of the off-site truck shipments for LANL. The number of these type of shipments may increase above the No Action levels for the Expanded Operations, Reduced Operations (driven by waste shipments) and Greener Alternatives, but the percentage is likely to remain about the same. For perspective on the regional context for these types of shipments, the percentage of truck shipments that carry hazardous chemicals or radioactive materials in the State of New Mexico has been estimated by state transportation officials to be about 10 percent, although some segments of highway, such as I–40, may be much higher.

Under the CT EIS proposed action, the peak traffic entering or exiting all 10 tracts could increase by a range of approximately 751 to 3,775 trips per day. Many of the current roads and intersections would have to be upgraded to accommodate the new traffic levels.

The draft SPD EIS (DOE 1998b), Lead Assembly Alternative, documents the additional transportation impacts should LANL, be selected for this activity. Plutonium dioxide would already be at LANL, so no shipping would be required for this material. LANL would receive uranium dioxide and other material needed to assemble mixed oxide (MOX) fuel bundles from a nuclear fuel fabricator and would ship MOX fuel assemblies to a reactor site. Approximately 20 shipments of radiative materials would be carried out by DOE. The total distance traveled on public roads by trucks carrying radioactive materials would be about 34,000 miles (55,000 kilometers). The dose to transportation workers from all transportation activities under this lead assembly alternative has been estimated at 1.5 person-rem; the dose to the public has been estimated at 10.3 person-rem. Accordingly, the incident-free transportation of radioactive material would result in 5.9×10^{-4} excess LCFs; among transportation workers and 5.1×10^{-3} excess LCFs in the total affected population over the duration of the transportation activities. The estimated number of nonradiological fatalities from vehicular emissions would be 1.5×10^{-4}. Estimates of the total ground transportation accident risks indicate a radiological dose to the population of 6.2 person-rem, resulting in a total population risk of 3.1×10^{-3} excess LCFs and traffic accidents resulting in 6.7×10^{-4} traffic fatality.

5.6.1.9 Human Health

The development of the CT EIS proposed action could bring as many as 900 new residents into closer proximity to LANL facilities at the DOE Los Alamos Area Office and DP Road Tracts, and another 2,200 residents and lodgers at the White Rock Tract. Commercial development could bring as many as 6,000 private-sector employees into existing radiation buffer zones at the DP Road, TA–21, and Airport Tracts. These developments would mean increased public exposures to radiological and chemical emissions from LANL, from normal operations and hypothetical accidents. A substantial increase in the public collective radiation dose would result.

Implementation of the Lead Assembly Alternative, analyzed in the draft SPD EIS (DOE 1998b), at LANL would contribute the following impacts. The expected number of excess LCFs as a result of the radiation released from these activities in the general population residing within 50 miles (80 kilometers) of LANL would be 1.2×10^{-5}. The expected number of excess LCFs to involved workers would be 0.011. The expected annual dose to the MEI is 9.0×10^{-3} millirem per year, which corresponds to an associated excess LCF risk of 4.5×10^{-9}. Transportation related to these activities would not be expected to result in any excess LCFs either. Thus, implementation of the lead assembly fabrication activities at LANL would pose no significant health risks to the public.

5.6.2 Unavoidable Adverse Impacts

Operating LANL under any alternative involves the release of small quantities of radioactive and hazardous materials via routinely monitored air and water effluent discharges. Analysis has shown these discharges to be of minimal consequence; nonetheless, they represent an impact that is unavoidable. Control measures commensurate with potential risk are in place, and in an evolutionary manner, seek to reduce these discharges to the lowest practical levels. Solid radioactive and hazardous waste, and sanitary wastes also result from routine operations, and must be treated and disposed. The active recycle, waste minimization, and waste avoidance programs at LANL continuously work to reduce the volume and types of these wastes. Potential disturbance of biological and cultural resources can result from operations, and restricted access to some traditional cultural properties might be viewed as adverse.

5.6.3 Irreversible and Irretrievable Commitments of Resources

Operations at LANL under the various alternatives require the consumption of a number of resources. Table 3.6.2–1 in chapter 3 shows the projected usage of water, natural gas, and electricity across the SWEIS alternatives. (These resources are also discussed by alternative in sections 5.2.9.2, 5.3.9.2, 5.4.9.2, and 5.5.9.2.) While deficiencies in some of the local distribution systems for gas and electricity were discussed in this analysis, no shortages in total regional supplies were noted. There also are many materials requirements for maintenance of facilities, and operations require the consumption of the entire range of expected products and materials, such as chemicals. There is an active recycling program at LANL; most products are expended or disposed. Approximately 43 square miles (111 square kilometers) are reserved for laboratory operations. A large amount of that area remains undisturbed, and development has been, and will continue to be, concentrated in areas of like operations. While it is theoretically possible to consider that the entire facility could be decommissioned and removed, operations, including waste disposal, are expected to continue into the foreseeable future. These lands are therefore removed from use for other purposes. An active environmental restoration program seeks to reduce the risk from past discharges of radioactive and hazardous materials; but, not all areas are expected to be restored to their original condition. LLW disposal at LANL places strict limitations on alternative or future uses of the disposal areas. The disposal sites would require monitoring and various forms of protective actions, including administrative access control, for an extended period of time.

5.6.4 Relationship Between Local Short-Term Uses of the Environment and the Maintenance and Enhancement of Long-Term Productivity

A decision to operate LANL under any alternative requires the commitment of resources that cannot be recovered, the acceptance of impacts from normal operations that release pollutants and cause disturbances. The national resource embodied in LANL, which is continually tapped by different entities throughout the U.S. as well as abroad, is used to work on problems involving national security, energy resources, environmental quality, and in science.

A large portion of the knowledge and capability necessary to support the nuclear weapons program resides at LANL. The program implemented by DOE, and as discussed in the SSM PEIS (DOE 1996d), has been reduced in size, refocused, and operations consolidated to a fewer number of sites.

CHAPTER 6.0
MITIGATION MEASURES

The regulations promulgated by the Council on Environmental Quality (CEQ) to implement the procedural provisions of NEPA (42 United States Code [U.S.C.] §4321) require that an EIS include a discussion of appropriate mitigation measures (40 Code of Federal Regulations [CFR] 1502.14[f]; 40 CFR 1502.16[h]). The term "mitigation" includes the following:

- Avoiding an impact by not taking an action or parts of an action
- Minimizing impacts by limiting the degree of magnitude of an action and its implementation
- Rectifying an impact by repairing, rehabilitating, or restoring the affected environment
- Reducing or eliminating the impact by preservation and maintenance operations during the life of the action
- Compensating for the impact by replacing or providing substitute resources or environments (40 CFR 1508.20)

This chapter describes mitigation measures that are built into the alternatives analyzed and those additional measures that will be considered by DOE to further mitigate the adverse impacts identified in chapter 5. These measures address the range of potential impacts of continuing to operate LANL (including those areas where the lack of information regarding resources or mechanisms for impact to resources results in substantial uncertainty in impact analyses). The mitigation measures built into the alternatives analyzed (section 6.1) are of two types: (1) existing programs and controls (including regulations, policies, contractual requirements, and administrative procedures); and (2) specific measures built into the alternatives that serve to minimize the effects of activities under the alternatives. The existing programs and controls are too numerous to list here; but a general description is provided, as well as the role of existing programs in operating LANL and pertinent examples of how these mitigate adverse impacts.

Additional mitigation measures that could further reduce the adverse impacts identified in chapter 5 are discussed in section 6.2. The description of these measures in this chapter does not constitute a commitment to undertake any of these measures. Any such commitments would be reflected in the Record of Decision (ROD) following this SWEIS, with a more detailed description and implementation plan in a Mitigation Action Plan following the ROD.

6.1 MITIGATION MEASURES INCLUDED IN THE SWEIS ALTERNATIVES

6.1.1 Existing Programs and Controls

The activities undertaken at LANL are performed within the constraints of applicable regulations, applicable DOE orders, contractual requirements, and approved policies and procedures. The laws and regulations applicable to federal facilities are discussed in chapter 7; many of these requirements are established with the intent of protecting human health and the environment. It is assumed that these or similar regulatory controls will be in place for the next 10 years. These regulations, when complied with, mitigate the potential adverse impacts of operations to the public, the worker, and the environment. For example, the *Clean Air Act* (CAA) (42 U.S.C. §7401) regulates air emissions and the *Clean Water Act* (33 U.S.C. §1251) regulates liquid effluent discharges in a manner designed to protect human health and reduce the adverse environmental effects of routine operations.

In addition to the regulations applicable to LANL, chapter 7 also discusses other requirements (including DOE orders and external standards and regulations that would not otherwise apply to federal facilities) that apply to operations at LANL through the contract between DOE and the University of California (UC). As discussed in chapter 7, these requirements are established and enforced through contractual mechanisms. As with the regulations that apply to LANL, it is assumed that these or similar controls will be in place for the next 10 years. These requirements also mitigate the potential for adverse impacts. For example, the application of DOE design standards results in more robust facility designs for modern nuclear facilities, which reduces the potential for catastrophic releases from such facilities in the event of earthquakes, high winds, or other natural phenomena. Similarly, the application of occupational safety and health regulations in 29 CFR 1900, and other standards promulgated by the American National Standards Institute (ANSI), the U.S. Department of Defense (DoD), and DOE, as well as the use of other life safety and fire safety codes and manuals, limit worker exposures to workplace hazards, which reduces the potential for adverse worker health effects.

DOE and LANL also have instituted policies and procedures that apply to work conducted at LANL that mitigate the potential adverse effects of operations; it is assumed that these or similar policies and procedures will continue over the next 10 years. These are numerous and include, but are not limited to:

- Procedures that control work conducted at LANL (to ensure that work conducted is planned and reviewed, funded, within the applicable regulations and requirements, within the range of risks accepted by DOE and UC, and is otherwise authorized)
- Policies regarding the knowledge, skills, and abilities of personnel assigned to perform hazardous work (including required training)
- Policies reflected in agreements with other entities (such as the Accords with the four Pueblos located nearest to LANL) that establish policies and protocols regarding consultations and other discussions regarding LANL activities
- Policies and procedures regarding the stoppage and restart of work where unexpected hazards or resources are identified (for example, the policies regarding recovery of information from archaeological sites uncovered by excavation)

Work controls reduce potential impacts by ensuring that work conducted is within the range of activities that have been studied for potential environmental and human health effects. Policies regarding the knowledge, skills, and abilities of personnel conducting work at LANL reduce potential impacts by ensuring that only personnel with an appropriate understanding of the work and its potential hazards may undertake that work (which minimizes the potential for adverse human health and environmental effects from inadvertent actions due to a lack of this understanding). Policies for consultations and discussions with other entities mitigate effects by providing an opportunity to avoid or change actions that could cause an adverse impact. For example, consultation with Pueblos could identify the potential to impact traditional cultural properties (TCPs) prior to implementing a construction project or operations and could identify alternative siting or operational approaches that would avoid the impact. Policies and procedures regarding the stoppage and restart of work are similar in effect to work controls; when unexpected situations occur that impose unexpected hazards or reveal unexpected resources (e.g., cultural resources), work is stopped (as soon as this can be done safely) until work plans and authorizations can be modified in consideration of the newly uncovered information. This reduces potential impacts in a manner similar to work controls, as discussed above.

DOE also has established programs and projects at LANL to increase the level of knowledge regarding the environment around LANL, health of LANL workers, health of the public around LANL, and the effects of LANL operations on these, as well as to avoid or reduce impacts and remediate contamination from previous LANL activities. These programs and projects reduce potential adverse impacts by providing for heightened understanding of the resources that could be impacted; avoidance of some impacts (where mechanisms for impact to specific resources are known and avoidable); early identification of impacts (which can enable stoppage or mitigation of the impacts); reduction of ongoing impacts; or providing for beneficial management opportunities for natural, cultural, and sensitive resources, where appropriate. It is assumed that such activities will continue for the next 10 years. Examples of these programs and projects are:

- The Environmental Surveillance and Compliance Program at LANL monitors LANL for permit and environmental management requirements. This program also includes evaluation of samples from various environmental media for radioactive materials and other hazardous materials locally and regionally (chapter 4, page 4–1). The data generated under this program are collected routinely and publicly reported at least annually, and these data are analyzed to determine regulatory compliance and to determine environmental trends over long periods of time.
- The Threatened and Endangered Species Habitat Management Plan is intended to provide long-range planning information for future LANL projects, and protect habitat at LANL for these species (section 4.5.1.6).
- A Natural Resource Management Plan is being developed (in various stages) at LANL to determine existing conditions of natural resources in the area (including expanded biomonitoring) and to recommend management measures that will restore, sustain, and enhance the biological quality and ecosystem integrity at LANL (section 4.5.1.6).
- Studies of public and worker health in and around LANL have been conducted (some by DOE and some by other agencies) to assess human health in the region and to assess the potential for adverse human health effects due to LANL operations (section 4.6).
- LANL is also implementing a Groundwater Protection Management Program Plan (GWPMPP) to assess current groundwater conditions and monitor and protect groundwater. A *Resource Conservation and Recovery Act* (RCRA) Hydrogeologic Workplan is also being implemented to supplement and verify existing information on the environmental setting at LANL and to collect analytical data on groundwater contamination (sections 4.3.2.1 and 4.3.2.2).
- The Safeguards and Security Program restricts unauthorized access to areas of LANL with high potential for impact to human health and the environment. Such access restrictions aid in limiting the potential for intentional or inadvertent actions that could result in environmental or human health effects (section 4.9.2.2).
- Emergency management and response capabilities at LANL provide for planning, preparedness, and response capabilities that can aid in containing and remediating the effects of accidents or adverse operational impacts (section 4.6.3.1).
- LANL's Fire Protection Program ensures that personnel and property are adequately

protected against fire or related incidents, including fire protection and life safety (section 4.6.3.3).

- Pollution Prevention and Waste Minimization Programs at LANL reduce the wastes generated and to some extent the effluents and emissions from facilities (section 2.1.2.1).
- Water and Energy Conservation Programs at LANL are intended to reduce use of these resources, which should assist in mitigating the effects of water withdrawal and electrical consumption that occasionally exceed supply.
- The Environmental Restoration (ER) Project at LANL (which includes decontamination and decommissioning [D&D]) was established to assess and remediate contaminated sites that either were or still are under LANL control (section 2.1.2.5). The ER Project serves an important role in reducing the potential for future impacts to human health and the environment due to legacy contaminants in the environment. It is assumed that the current mitigation practices used in remediation actions will continue to be used (section 2.1.2.5).
- Electric power reliability is an issue under all alternatives due to the limited supply lines and the age of the distribution system equipment, as well as the limits of the on-site supplemental power supply (section 4.9.2.1). DOE is evaluating a proposed action that would bring a third power line (from the Norton substation) to LANL (chapter 1, section 1.6.3.1).

While this list is not all-inclusive, it does reflect the importance of these programs in mitigating the potential adverse impacts of operating LANL.

6.1.2 Specific Mitigation Measures Incorporated in the SWEIS Alternatives

Several specific mitigation measures are included in the SWEIS alternatives. Unless otherwise noted below, the analyses in chapter 5 assume that these measures are implemented. These specific measures are:

- *Development and Use of a Dedicated Transportation Corridor Between TA–55 and TA–3 (TA–55 and TA–3, Expanded Operations Alternative, section 3.2.1, section 5.3.10, and volume II, part II)*. The proposed transportation corridor is included in the Expanded Operations Alternative to mitigate the on-site transportation risk and inconvenience to the public (due to road closures) that would be attributed to the increase in transportation between TA–55 and the Chemistry and Metallurgy Research (CMR) Building under this alternative. The analysis in the Expanded Operations Alternative is very conservative because it includes the impacts of constructing the road and impacts of transport on existing roads. If the road is not constructed, the transportation risk would be that analyzed in section 5.3.10 for on-site shipments. The impacts attributable to constructing the road (see volume II, part II and section 5.3.5) would not be incurred. If the road is built and used, the impacts due to road construction would be the same as those analyzed, and the on-site transportation risk would be reduced because shipments between TA–55 and the CMR Building would no longer routinely use public roads. This measure would not be implemented under the Preferred Alternative.
- *The Santa Fe Relief Route (All LANL Facilities, All Alternatives, sections 5.1.10, 5.2.10, 5.3.10, 5.4.10, 5.5.10, and appendix F)*. DOE has made the agreed upon contributions to construction of this route and continues to work with state and

local governments to ensure its completion. This route is expected to be available for use in 1998. The transportation impact analyses in this SWEIS address impacts for use of existing routes as well as use of the relief route.

- *CMR Building Upgrades (CMR Building at TA–3, All Alternatives, section 3.1.3).* DOE is working to upgrade the CMR Building to maintain existing capabilities and improve safety features, and completion of these upgrades is presumed in the impact analyses.
- *Planned Maintenance and Refurbishment Activities (e.g., Plutonium Facility at TA–55 and Sigma at TA–3, All Alternatives, sections 2.1.2.3, 3.1.1, and 3.1.5).* It is assumed that DOE maintenance of existing facilities in use at LANL will continue in a manner that maintains or improves (reduces) the level of risk associated with facility operations.
- *Radioactive Liquid Waste Treatment Upgrades (TA–50, All Alternatives, sections 3.1.14, 4.3, 5.1.3, 5.2.3, 5.3.3, 5.4.3, and 5.5.3).* It is assumed that the planned treatment upgrades to TA–50 will proceed, resulting in improved quality of effluent from this facility.
- *Effluent Reduction Activities (All LANL Facilities, All Alternatives, sections 4.3, 5.1.3, 5.2.3, 5.3.3, 5.4.3, and 5.5.3).* It is expected that activities to reduce the number of outfalls and the total effluent from these outfalls will continue, as presented in section 4.3.
- *Phased Containment for Dual Axis Radiographic Hydrodynamic Test (DARHT) Facility (One of the High Explosives [HE] Firing Sites, All Alternatives, section 3.1.10).* Implementation of the phased containment approach, as described in the DARHT Final EIS (DOE 1995) and ROD (60 *Federal Register* [FR] 53588) is assumed in the SWEIS impact analyses.
- *Design of the Long-Pulse Spallation Source (LPSS) (TA–53, Expanded Operations and Greener Alternatives, section 3.2.11).* The air emissions associated with operations in this proposed experimental facility are dominated by the "activation" of air in the path of the proton beam. The design of the facility is to include evacuation (removal) of much of the air in the beam path as well as a short enough beam path to limit the emissions from this operation so that it contributes, at most, 1 millirem per year to the facility and site-wide maximally exposed individual (MEI).

6.2 OTHER MITIGATION MEASURES CONSIDERED

In addition to those mitigation measures described in section 6.1, other feasible mitigation measures considered in the preparation of this SWEIS are presented in this section. Those specific measures are:

- *Eliminate Public Access to Part or All of LANL*. At various times DOE has considered the possibility of closing public access to part or all of the LANL site. While this is typically suggested for security reasons, such an action would also tend to reduce public health risk by removing access to on-site locations that contribute most to public health risk. While such an action could potentially reduce public health consequences, it could also substantially alter traffic patterns and loadings on the remaining public roads in the area and could have other positive and negative effects. A more detailed NEPA analysis of the potential effects of this type of action would be necessary before it could be implemented.
- *Land Transfers and Financial Assistance*. Transfers of portions of LANL land are being examined, as discussed in section 4.1.1.4. Such action would provide land resources that could be used to reduce

economic dependence on LANL and/or provide the means for growth in housing, parks, and recreational space. Thus, land transfers could mitigate the effect of changes in LANL employment and spending on the area's economy. At times, financial assistance has been provided to communities near LANL for similar reasons (community development, funding for community services, etc.). While land transfers are neither proposed or analyzed in this SWEIS, such actions could mitigate the socioeconomic impacts presented in chapter 5. On May 6, 1998, DOE published a Notice of Intent (NOI) to prepare an EIS for the Proposed Conveyance and Transfer of Certain Land Tracts in the *Federal Register* (63 FR 25022).

- *Extensive Ethnographic Study.* An extensive ethnographic study regarding the traditional and cultural practices and resources in the LANL area could increase knowledge of specific TCPs at LANL and could provide opportunities for mitigation of impacts to specific TCPs. Attempts to identify specific TCPs at LANL have encountered concerns from traditional groups because of the potential for increased risk to these resources if they are identified.
- *Develop a Cultural Resources Management Plan*. Such a plan would include studies to increase the level of knowledge regarding potential shrapnel and vibration damage to prehistoric and historic resources near firing sites, existing levels of contamination for prehistoric and historic resources and plans to avoid levels that would limit data recovery, plans for management of former nuclear weapons complex properties, and implementation of programmatic agreements with the State Historic Preservation Office(r) (SHPO).
- *Develop a Wildfire Management Plan for the LANL Site*. Such a plan would reduce the fuel loading surrounding the site and around individual facilities that have moderate or higher vulnerability to burning as a result of wildfire. The probability of an approaching wildfire encroaching upon the site can be reduced by removing and thinning vegetation on the site boundary and within the site. Ongoing efforts to reduce the vegetation at the site boundary exist that would be accelerated. The vulnerability of individual facilities depends upon the amount and height of the exterior fuel loading and its proximity to the facility (see "Evaluation of Building Fires" in volume III, appendix G, section G.5.4.4). Consideration is being given to reducing the vulnerability of individual facilities that contribute to potential public exposure. Long-term actions would be taken to reduce the fuel loads in the forested areas surrounding LANL, and a forest and land management program would be undertaken to prevent or mitigate the potential for large wildfires to occur. In the near term, mitigation actions, such as for TA–54, will be taken to ensure that the wildfire risk to this facility is reduced to low or extremely low prior to the start of the 1999 fire season.
- *Limited Power Supply.* DOE and other regional electric power users continue to work with suppliers to remedy foreseeable power supply and reliability issues. The impact analyses in this SWEIS emphasize the severity of these issues and the consequences if they are not resolved. Solutions to power supply issues are essential to mitigate the effects of power demand under all alternatives. DOE is committed to measures that will conserve energy and avoid, or at least minimize, periods of brownouts. Some of the measures being contemplated by DOE include: (1) limiting operation of large users of electricity to periods of low demand, (2) reduced operation of low-energy demonstration accelerator (LEDA) (not implement all phases of this project), and (3) contractual mechanisms to bring additional electric power to the region.

CHAPTER 7.0
APPLICABLE LAWS, REGULATIONS, AND OTHER REQUIREMENTS

7.0 INTRODUCTION

As part of the NEPA process, the SWEIS must consider if actions described under its alternatives would result in a violation of any federal, state, or local laws or requirements (40 Code of Federal Regulations [CFR] 1508.27) or require a federal permit, license, or other entitlement (40 CFR 1502.25). This chapter provides a baseline summary assessment of the major existing environmental requirements, agreements, and permits that relate to continuing operations at LANL.

Requirements governing operations at LANL arise primarily from six sources: Congress, federal agencies, executive orders, the New Mexico State Legislature, state agencies, and local governments. In general, the federal statutes establish national policies, create broad legal requirements, and authorize federal agencies to create regulations that conform to the statute. Detailed implementation of these statutes is delegated to various federal agencies, such as DOE, the U.S. Department of Transportation (DOT), and the EPA. For many environmental laws under the jurisdiction of EPA, state agencies may be delegated responsibility for the majority of program implementation activities, such as permitting and enforcement, but EPA usually retains oversight of the delegated program.

In addition to implementing some federal programs, state legislatures develop their own laws. In New Mexico, the statutes passed by the New Mexico State Legislature are found in the New Mexico Statutes Annotated, and regulations are found in the New Mexico Administrative Code (NMAC). State statutes, much like federal statutes, establish broad policies and legal requirements. State regulations, developed by state agencies, establish specific legal requirements as authorized by the statutes.

Executive orders establish policies and requirements for federal agencies. Executive orders are applicable to executive branch agencies, but do not have the force of law or regulation.

Regulatory agreements and compliance orders may also be initiated to establish responsibilities and time frames for federal facilities to come into compliance with provisions of applicable federal and state laws. There are also other agreements, memorandums of understanding, or formalized arrangements that establish cooperative relationships and requirements.

DOE has authority to regulate some environmental activities, as well as the health and safety aspects of operation of its nuclear facilities. The *Atomic Energy Act of 1954* (AEA), as amended (40 United States Code [U.S.C.] §2011), is the principal authority for DOE regulatory activities not externally regulated by other federal or state agencies. Regulation of DOE activities is primarily established through the use of DOE orders and regulations. External environmental laws, regulations, and executive orders can be categorized as applicable to broad environmental planning and consultation requirements, or as applicable to regulatory environmental protection and compliance activities, although some requirements are applicable to both planning and operations compliance.

7.1 DOE REGULATORY AUTHORITIES FOR ENVIRONMENT, SAFETY AND HEALTH

7.1.1 *Atomic Energy Act of 1954*

The AEA (42 U.S.C. §2011 *et seq.*) makes the federal government responsible for regulatory control of the disposal of radioactive waste, as well as production, possession, and use of three types of radioactive material: source, special nuclear, and byproduct material. Regulations promulgated by the U.S. Nuclear Regulatory Commission (NRC) under the AEA establish standards for the management of these radioactive materials, licensing of nuclear facilities, and the protection of the public and property against radiation. The AEA authorizes DOE to set radiation protection standards for itself and its contractors for DOE nuclear facilities, and provides exclusions from NRC licensing for defense production facilities. NRC regulates private and commercial nuclear activities, but currently has no regulating authority at most DOE facilities. In December 1996, DOE announced that it would begin a process of transferring oversight of nuclear safety to the NRC for all DOE nuclear facilities (DOE 1996). The transfer will require legislative action.

The AEA authorizes DOE to establish standards that protect health and minimize danger to life or property from activities under DOE's jurisdiction. The mechanisms through which DOE manages its facilities are the promulgation of regulations and issuance of DOE orders and associated standards and guidance. Requirements for environmental protection, safety and health are implemented at DOE sites, primarily through contractual mechanisms that establish the applicable DOE requirements for management and operating contractors.

DOE orders apply to LANL through the management and operating contract with the University of California (UC) (DOE 1997b). The applicable DOE orders or parts thereof, and applicable external and internal standards, are listed and maintained current in Appendix G of the contract and are enforced and modified through contractual mechanisms. Appendix G of the contract establishes a wide range of internal requirements for business systems and reporting, safeguards and security, and environment, safety, and health. In the current contract (effective October 1, 1997), all applicable environment, safety, and health protection standards (including both external and DOE requirements) are found in a set of Work Smart Standards in Appendix G of the contract.

The U.S. Department of Labor Occupational Safety and Health Administration (OSHA) regulations generally do not directly apply to DOE nuclear facilities and management and operating contractors. However, for protection of worker safety and health, the Work Smart Standards adopted in Appendix G of the contract include the applicable occupational safety and health regulations (29 CFR 1900); American National Standards Institute (ANSI) standards; National Fire Protection Association (NFPA) standards; U.S. Department of Defense (DoD) standards (for explosives operations); DOE orders (for firearms safety, explosives safety, nuclear facilities safety, pressure safety, construction safety, packaging and transportation, and emergency management); various other codes, manuals, and standards for safety; and various LANL internal standards. This set of Work Smart Standards contractually establishes worker safety and health protection requirements for LANL, as well as emergency response and public protection requirements where there is no external regulatory authority.

Nuclear safety regulations are found in Title 10 of the CFR. Several nuclear safety rules and environmental procedural rules are in effect (for example, 10 CFR 835, *Occupational Radiation*

Protection), and more are in final stages of promulgation. Nuclear safety regulations are effective under the schedule and implementing requirements in each rule, regardless of whether they are included in the contract. DOE contractors are also required to comply with all applicable external laws and regulations, regardless of contract language.

The principal DOE orders having a direct impact on environmental protection and compliance activities at LANL are summarized in the following sections.

7.1.1.1 *DOE Order 451.1A, National Environmental Policy Act Compliance Program*

This order establishes DOE internal requirements and responsibilities for implementing NEPA, the *Council on Environmental Quality (CEQ) Regulations Implementing the Procedural Provisions of NEPA* (40 CFR 1500 through 1508), and the *DOE NEPA Implementing Procedures* (10 CFR 1021).

7.1.1.2 *DOE Order 5400.1, General Environmental Protection Program*

This order establishes the environmental protection program requirements, authorities, and responsibilities for DOE operations for ensuring compliance with applicable federal, state, and local environmental protection laws and regulations, executive orders, and internal DOE policies. This order provides for environmental protection standards, notification of and reporting requirements for discharges and unplanned releases, environmental protection and program plans, and environmental monitoring and surveillance requirements. It establishes formal recognition that DOE's environmental management activities are extensively, but not entirely, regulated by EPA, state, and local environmental agencies, and it provides requirements for satisfying these externally imposed regulations. In addition, it establishes requirements for those environmental protection programs that are not externally regulated.

7.1.1.3 *DOE Order 5400.5, Radiation Protection of the Public and Environment*

This order establishes standards and requirements for operations of DOE and its contractors with respect to protection of members of the public and the environment against undue risk from ionizing radiation. This order provides for general standards; requirements for radiation protection of the public and the environment; derived concentration guides (DCGs) for air and water; and guidelines, limits, and controls for residual radioactive materials. The order also establishes DOE's objective to operate its facilities and conduct its activities so that radiation exposures to members of the public are maintained within the limits established by this order, and to control radioactive contamination through the management of DOE's real and personal property. The requirements of this order are incorporated into the proposed 10 CFR 834, which is being promulgated as a nuclear safety regulation.

7.1.1.4 *DOE Order 5820.2A, Radioactive Waste Management*

DOE Order 5820.2A establishes the policies, guidelines, and minimum requirements by which DOE and its contractors manage radioactive waste, mixed waste, and contaminated facilities. This order establishes the DOE policy that radioactive and mixed wastes be managed in a manner that ensures protection of the health and safety of the public, DOE, contractor employees, and the environment. In addition, the generation, treatment, storage, transportation, and/or disposal of radioactive wastes, and the other pollutants or hazardous substances they contain, must be accomplished in a manner that minimizes the generation of such wastes across program office functions and complies with all applicable federal, state, and local environmental, safety, and health laws and regulations and DOE requirements.

These DOE orders are implemented by DOE, and by UC/LANL (through contractual direction). With the exception of radioactive materials, all environmental protection and compliance activities at LANL are externally regulated by other federal and state agencies. Environmental planning and consultation requirements are applicable to DOE and LANL in accordance with the specific language in each law, regulation, or executive order. The above-listed DOE orders and any applicable nuclear safety regulations are discussed in the following sections as they relate to external environmental planning and consultation requirements, or as applicable to regulatory environmental protection and compliance activities.

7.2 Laws, Regulations and Executive Orders Related to Environmental Planning and Consultation

7.2.1 *National Environmental Policy Act of 1969*, as Amended and Executive Order 11514, as Amended by Executive Order 11991

The NEPA of 1969, as amended (42 U.S.C. §4321 *et seq.*), requires federal agencies to evaluate the effect proposed actions would have on the quality of the human environment and to document this evaluation with a detailed statement. NEPA requires consideration of environmental impacts of an action during the planning and decision-making stages of a project.

Implementing regulations for NEPA have been developed by the CEQ, which oversees the NEPA process for the Executive Branch of the federal government. These regulations (40 CFR 1500 through 1508) set forth the general requirements that federal agencies must follow. DOE also has issued agency NEPA implementing procedures that are codified at 10 CFR 1021.

There are other environmental and cultural resource consultation requirements that must be complied with to ensure NEPA compliance. Each of these other laws or executive orders has unique review and compliance procedures established that are independent of NEPA. Accordingly, although compliance with these statutes comprises an important subset of the NEPA process, compliance with applicable requirements is mandatory for all projects, independent of NEPA. For example, under NEPA review, proposed actions are evaluated for possible effects on cultural resources (archaeological sites or historic buildings) in accordance with the *National Historic Preservation Act of 1966* (16 U.S.C. §470); for their potential impact on floodplains or wetlands in accordance with relevant executive orders; and for effects on threatened, endangered, or sensitive species in accordance with the *Endangered Species Act* (16 U.S.C. §1531). A discussion of the planning and consultation requirements for these types of resources is found in the following sections.

Executive Order 11514, *Protection and Enhancement of Environmental Quality,* as amended by Executive Order 11991, requires federal agencies to monitor and control their activities continually to protect and enhance the quality of the environment. The executive order contains requirements to ensure that federal agencies include the public in the decision-making process. The DOE NEPA implementing regulations (10 CFR 1021) and DOE Order 451.1A address this executive order through implementation of 40 CFR 1500–1508.

7.2.2 *Endangered Species Act*, as Amended, and Related Requirements

This act requires that federal agencies ensure that any actions authorized, funded, or carried out by federal agency are not likely to jeopardize the continued existence of any threatened or endangered species or destroy or adversely modify critical habitat. The act is jointly administered by the U.S. Department of Commerce and the U.S. Department of the Interior (DOI). The *Endangered Species Act* (16 U.S.C. §1531 *et seq.*) requires federal agencies to consult with the U.S. Fish and Wildlife Service (FWS). While biological assessment procedures may be integrated into the NEPA process, the consultation requirements with FWS must still be followed for any LANL activity with the potential to affect threatened or endangered species. Implementing regulations are delineated in *Endangered and Threatened Wildlife and Plants* (50 CFR 17) and *Interagency Cooperation* (50 CFR 402). The state has also issued regulations pertaining to plants specific to the state entitled, *Endangered Plants* (75-6-1, NMSA 1978).

There are several additional federal statutes that provide protection to sensitive or otherwise regulated wildlife species, two of which are the *Migratory Bird Treaty Act*, as amended (16 U.S.C. §703), and the *Bald Eagle Protection Act*, as amended (16 U.S.C. §668). The first act protects migratory birds by specifying mode of harvest, hunting seasons, and bag limits. The act is intended to protect birds that have common migratory patterns within the U.S., Canada, Mexico, Japan, and Russia. Implementing regulations are found in *Taking, Possession, Transportation, Sale, Purchase, Barter, Exportation, and Importation of Wildlife and Plants* (50 CFR 10) and *Migratory Bird Hunting* (50 CFR 20). The second act makes it unlawful to take (capture, kill, or destroy), molest, or disturb bald (American) and golden eagles, their nests, or their eggs anywhere in the U.S. A permit must be obtained from the DOI to relocate a nest that interferes with resource development or recovery operations. Implementing regulations are delineated in *Eagle Permits* (50 CFR 22).

The New Mexico *Wildlife Conservation Act* (17-2-37 *et seq.*, NMSA 1978) also establishes requirements for protecting wildlife, primarily related to taking for sport purposes and permits for collecting and use.

DOE meets the requirements of these laws by contacting and consulting with federal and state agencies responsible for protecting animal and plant species within the State of New Mexico. FWS, the U.S. Forest Service (USFS), the National Park Service (NPS), the Bureau of Indian Affairs (BIA), the National Biological Service, New Mexico Environment Department (NMED), and the New Mexico Department of Game and Fish (NMDGF), are contacted regarding concerns each agency may have about LANL activities.

In accordance with Section 7 of the *Endangered Species Act*, a biological assessment and Section 7 Endangered Species Consultation for activities included in the SWEIS are being conducted with the FWS.

7.2.3 *National Historic Preservation Act*, as Amended

This act provides that sites with significant national historic value be placed on the National Register of Historic Places (NRHP). Government agencies must locate and inventory historic properties and cultural resources under their jurisdiction prior to undertaking an activity that might harm them, with the intent of minimizing such harm through appropriate mitigation actions. As required by Section 106 of the *National Historic Preservation Act* (16 U.S.C. §470), proposed LANL activities are evaluated in consultation with the State Historic Preservation Office(r) (SHPO) for possible effects on cultural resources. Most surveys are conducted on DOE property; however, when appropriate, surveys are conducted on land owned by other federal agencies, state-owned land, tribal lands, or other private holdings, and LANL holds discussions, as appropriate, with various Indian tribes to determine how new LANL activities might affect cultural resources. The tribes are also requested to provide input on what mitigation measures they want implemented before LANL begins an activity. DOE must also obtain comments from the Advisory Council on Historic Preservation prior to undertaking a potentially damaging activity at LANL. Implementing regulations include *Protection of Historic and Cultural Properties* (36 CFR 800). Consultation requirements are applicable to actions discussed in the SWEIS, as well as any future activities at LANL.

7.2.4 *National Historic Preservation,* Executive Order 11593

This executive order requires federal agencies, including DOE, to locate, inventory, and nominate properties under their jurisdiction or control to the NRHP if those properties qualify. DOE is required to provide the Advisory Council on Historic Preservation the opportunity to comment on possible impacts of a proposed activity on any potentially eligible or listed resources.

7.2.5 *American Indian Religious Freedom Act of 1978*

This act establishes that it is U.S. policy to protect and preserve for American Indians their inherent right of freedom to believe, express, and exercise their traditional religions, including access to sites, uses and possession of sacred objects, and the freedom to worship through ceremonies and traditional rites. In accordance with the *American Indian Religious Freedom Act* (42 U.S.C. §1996), LANL activities are planned so that they do not adversely affect the practice of traditional religions. Tribal groups are notified of projected construction activities and are requested to inform DOE if any activity will affect a traditional cultural property.

7.2.6 *Native American Graves Protection and Repatriation Act of 1990*

This act states that tribal descendants shall own American Indian human remains and cultural items discovered on federal lands after November 16, 1990. When items are discovered during an activity on federal lands, the activity is to cease and appropriate tribal governments are to be notified. Work on the activity can resume 30 days after the receipt of certification that notice has been received by the tribal governments. As required by the *Native American Graves Protection and Repatriation Act* (NAGPRA) (25 U.S.C. §3001), LANL has completed a summary list of cultural items excavated in the past from archaeological sites on LANL property, including prior to 1990. Copies of this summary were sent to local Pueblos having ancestral ties to the Pajarito Plateau. This summary provides a basis for future repatriation of cultural items to tribal governments.

7.2.7 *Archaeological Resource Protection Act*, as Amended

The *Archaeological Resource Protection Act* (16 U.S.C. §470aa) requires the preservation and management of archaeological resources on lands administered by federal agencies. LANL maintains a cultural resources management database, and this information continues to be used in planning remediation and other construction activities to prevent damage to or destruction of archaeological resources at LANL. Archaeological survey reports are prepared by LANL cultural resource specialists and are submitted to Native American communities for review and concurrence.

7.2.8 *Indian Sacred Sites*, Executive Order 13007

Executive Order 13007 requires: "In managing federal lands, each executive branch agency with statutory or administrative responsibility for the management of federal lands shall, to the extent practicable, permitted by law, and not clearly inconsistent with essential agency functions, (1) accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners and (2) avoid adversely affecting the physical integrity of such sacred sites. Where appropriate, agencies shall maintain the confidentiality of sites." Requests by the Pueblos to use sacred sites on LANL are accommodated to the extent practicable, and consultation regarding potential impacts to sacred sites is conducted through the NEPA review process and through ongoing processes established in the Pueblo Accords and Cooperative Agreements, which are discussed below.

7.2.9 Pueblo Accords

Four federally recognized Indian tribes, the Pueblos of Cochiti, Jemez, Santa Clara, and San Ildefonso, have special relationships with the land now occupied by LANL. Federal laws and executive orders guarantee tribal members access to religious sites and recognize tribal rights to cultural properties, burial materials, and other articles of antiquity. However, Congress has assigned responsibilities to DOE that preclude open access to LANL land. Thus, some of the tribes' interests in, and uses for LANL land are difficult to reconcile.

To achieve mutual goals of improved understanding and cooperation, the four Pueblos and DOE are recognized as sovereign entities that will interact with one another on a government-to-government basis. DOE and each of these four Pueblos have executed formal accord documents setting forth these relationships (DOE 1992a, DOE 1992b, DOE 1992c, and DOE 1992d). The governor of each Pueblo signed an accord on behalf of the Pueblo. Each accord was also signed by the Assistant Secretary for Defense Programs on behalf of DOE and was approved as to form by the Area Director of the BIA, DOI.

The accords provide a framework for government-to-government relationships between each of the Pueblos and DOE. Further, the accords identify general procedures by which the sovereign entities will interact. By signing the accords, DOE has made a commitment to provide information and involve the Pueblos in long-range planning and decisions. The accords state DOE's commitment to working with its contractors and subcontractors and with other federal, state, and local agencies to clarify the roles and responsibilities of these entities that appear to conflict or overlap as they relate to the Pueblos.

DOE has also executed Cooperative Agreements with each of the four Pueblos that provide funding to the tribes for cooperative activities (DOE 1993, DOE 1994a, DOE 1994b, and DOE 1997a). UC, which operates LANL for DOE, also signed Cooperative Agreements with the Pueblos of Jemez, Cochiti, San Ildefonso, and Santa Clara (UC 1994a, UC 1994b, UC 1994c, and UC 1996). The agreements address Pueblo participation in health and safety matters; in LANL activities concerning the SWEIS and other NEPA activities; in environmental restoration, waste and environmental planning and management; and in other cooperative and collaborative efforts.

7.2.10 *Protection of Wetlands*, Executive Order 11990, and *Floodplain Management*, Executive Order 11988

Executive Order 11990 requires government agencies to avoid short- and long-term adverse impacts to wetlands whenever a practicable alternative exists. Executive Order 11988 directs federal agencies to establish procedures to ensure that the potential effects of flood hazards and floodplain management are considered for any action undertaken. Impacts to floodplains are to be avoided to the extent practicable. DOE issued regulations (10 CFR 1022) that establish procedures for compliance with these executive orders. DOE follows these regulations in evaluating proposed actions for wetlands and floodplain impacts. No floodplain/wetlands impacts were identified for the SWEIS that require coordination under these executive orders.

7.2.11 *Environmental Justice*, Executive Order 12898

This order directs each federal agency to identify and address disproportionately high adverse human health or environmental impacts on minority and low-income populations resulting from an agency's programs, policies, or activities. The order further directs each federal agency to collect, maintain, analyze, and make information publicly available on the race, national origin, and income level of populations in areas surrounding facilities or sites expected to have a substantial environmental, human health, or economic effect on these populations. This requirement applies when such facilities or sites become the subject of a substantial federal environmental administrative or judicial action. Environmental justice impacts are being identified and addressed through the SWEIS, and the policies and data analysis requirements of this executive order remain applicable to future actions at LANL.

7.2.12 New Mexico Environmental Oversight and Monitoring Agreement

The Environmental Oversight and Monitoring Agreement, known as the Agreement in Principle (AIP), between DOE and the State of New Mexico, provides for technical and financial support by DOE for state activities in environmental oversight, monitoring, access, and emergency response. The agreement, which was initially signed in October 1990, covers Los Alamos and Sandia National Laboratories, the Waste Isolation Pilot Plant (WIPP), and the Inhalation Toxicology Research Institute. Under the agreement, NMED is the lead state agency and provides independent environmental monitoring and emergency planning review services related to all DOE activities at these sites in New Mexico. On October 2, 1995, DOE and NMED extended the AIP for an additional 5 years (DOE 1995).

7.2.13 *Recreational Fisheries*, Executive Order 12962

This order directs federal agencies to improve the quantity, function, sustainable productivity, and distribution of U.S. aquatic resources for increased recreation fishing opportunities; establishes a National Recreational Fisheries Coordination Council and mandates the preparation of a comprehensive Recreational Fishery Resources Conservation Plan; requires federal agencies to aggressively work to identify and minimize conflicts between recreational fisheries and their respective responsibilities under the *Endangered Species Act of 1973*; and expands the role to the Sport Fishing and Boating Partnership Council.

7.2.14 *Migratory Bird Treaty Act*

This act (16 U.S.C. §703) makes it unlawful to pursue, hunt, take, capture, kill (or attempt any of the preceding) any migratory bird or nest or eggs of such bird.

7.3 LAWS, REGULATIONS, AND EXECUTIVE ORDERS RELATED TO REGULATORY ENVIRONMENTAL PROTECTION AND COMPLIANCE

Regulatory environmental protection requirements are designed to protect human health and the environment, including the air, water, and land. Environmental protection statutes and regulations derived from authorities in statutes: (1) create procedures for examining actions that may harm the environment before carrying out that action; (2) establish standards that protect human health and the environment; (3) provide limits for releases into the environment; and (4) create management requirements for specific substances (e.g., asbestos and pesticides).

Federal Compliance with Pollution Control Standards, Executive Order 12088, amended by Executive Order 12580, requires federal agencies, including DOE, to comply with applicable administrative and procedural pollution control standards established by, but not limited to, the *Clean Air Act (CAA)*, *Noise Control Act*, *Clean Water Act*, *Safe Drinking Water Act*, *Toxic Substance Control Act*, and the *Resource Conservation and Recovery Act* (RCRA). In general, DOE and LANL must comply with applicable federal and state requirements to the same extent as any other entity. Noncompliance with these requirements can lead to enforcement actions.

Since LANL was constructed and began operations in the 1940's, before the advent of current environmental requirements, operational nuclear safety and national security were the dominant factors in the early design and operation of facilities. With the enactment of environmental laws and regulations from the 1960's to the present, resources and philosophies have changed to shift to a greater emphasis on environmental protection and achieving compliance with all applicable environmental requirements. Due to its long history, LANL has had difficulty in achieving compliance with some regulatory requirements, and has a legacy of environmental clean-up requirements from past management practices for waste, spills, and releases. Several compliance orders and agreements are also in effect with regulatory agencies to bring LANL into full compliance with specific regulatory requirements.

Depending on the regulatory background and framework of each federal and state law, there may be a primary regulatory enforcement authority at the federal level or at the state level. For some environmental resources, there may be both federal and state laws with applicable requirements, or DOE orders and regulations may be the primary considerations. Permitting for emissions and/or effluent discharges may also be at the federal level, state level, or both levels.

Applicable regulatory environmental laws and regulations can be categorized by media into air, water, land (which includes waste management, toxic substances, pollution prevention, and environmental restoration), and community right-to-know and emergency planning. For each resource category, there is a framework consisting of federal, state, local or DOE order requirements, which together regulate operations at LANL.

7.4 AIR RESOURCES

7.4.1 *Clean Air Act*, as Amended

The CAA (42 U.S.C. §7401 *et seq.*) establishes air quality standards to protect public health and the environment from the harmful effects of air pollution. The act requires establishment of national standards of performance for new stationary sources of emissions limitations for any new or modified structure that emits or may emit an air pollutant, and standards for emission of hazardous air pollutants (HAPs). In addition, the CAA requires that specific emission increases be evaluated to prevent a significant deterioration in air quality.

The *Clean Air Act Amendments of 1990*, signed into law on November 15, 1990, both enhanced and expanded existing authorities and created new programs in the areas of permitting, enforcement, operations in nonattainment areas (areas not meeting air quality standards), control of acid rain, regulation of air toxins, mobile sources, and protection of the ozone layer. Section 118 of the act and Executive Order 12088 require that each federal agency, such as DOE, with jurisdiction over any property or facility that might result in the discharge of air pollutants, comply with "all federal, state, interstate, and local requirements" with regard to the control and abatement of air pollution to the same extent as any nongovernmental entity.

EPA is the regulating authority for the CAA. However, EPA has granted the State of New Mexico primacy for regulating air quality under an approved State Implementation Plan (SIP). Authority for implementing the regulations promulgated for stratospheric ozone protection and the accidental release provisions of the act have not yet been delegated to the state. EPA also administers the National Emission Standards for Hazardous Air Pollutants (NESHAP) for radioactive emissions, including radon (subparts B, H, I, K, Q, R, T, and W). In New Mexico, all of the CAA regulations, with these exceptions, have been adopted by the state as part of the SIP, and are regulated under the *New Mexico Air Quality Control Act* (74-6-1, NMSA 1978).

NESHAP limits the radiation dose to the public from airborne radionuclide emissions from DOE facilities to 10 millirem per year effective dose equivalent (40 CFR 61.92). The standards also prescribe emission monitoring and test procedures for determining compliance with the 10 millirem per year standard, and reporting and permit provisions. EPA issued Notices of Noncompliance to DOE in 1991 and 1992 for not meeting all the provisions of 40 CFR 61, Subpart H. A Federal Facilities Compliance Agreement signed June 13, 1996, with EPA Region 6, provided an enforceable mechanism for bringing LANL into compliance (EPA 1996a). The compliance agreement required full compliance for all sources by March 1997, and LANL achieved full compliance in June 1996. In November 1994, Concerned Citizens for Nuclear Safety (CCNS) filed a CAA citizens' suit against DOE and UC, alleging LANL was not in compliance with Subpart H. In January 1997, DOE and UC entered into both a settlement agreement and consent decree. Highlights of the settlement agreement and consent decree include DOE-funded independent technical audits of LANL's radionuclide air emissions compliance program, the addition of some environmental monitoring stations, and quarterly public meetings conducted by UC on the environment.

DOE Order 5400.5, *Radiation Protection of the Public and the Environment*, also incorporates the EPA NESHAP standard for public doses from air emissions and provides for additional monitoring and evaluation of total public radiation dose from other pathways. Unplanned releases of radioactive effluents to the air are also reported and analyzed under provisions of DOE Order 5400.5. LANL has reported 13 air releases of radioactive materials through effluent stacks in the period 1991 through 1996. These reported releases usually involved a higher than normal operational limit radionuclide measurement determined through stack monitoring processes in place, or an unplanned release. These have usually included small quantities of tritium, and also occasionally very small quantities of other radionuclides. Only one release of tritium, in January 1994, exceeded the *Comprehensive Environmental Response, Compensation, and Liability Act* (CERCLA) (42 U.S.C. §9601) reportable quantity. All air releases were analyzed for impact on the environment and the public both in terms of dose and need for corrective action in accordance with DOE requirements in DOE Order 5400.5, DOE Order 232.1, and 40 CFR, Subpart H.

The federal regulations promulgated to implement the requirements of CAA Title VI, "Stratospheric Ozone Protection," are codified in *Protection of Stratospheric Ozone* (40 CFR 82). The primary purpose of these regulations is to eliminate the production of certain ozone-depleting substances and require users of the substances to reduce emissions to the atmosphere through recycling and mandatory use of certified maintenance technicians. These requirements are applicable to LANL, and are implemented accordingly.

On June 20, 1996, EPA promulgated *Accidental Release Prevention Requirements: Risk Management Programs* under CAA, Section 112 (r)(7), which amended 40 CFR 68. The intent of this regulation is to prevent accidental releases to the air and mitigate the consequences of such releases by focusing prevention measures on chemicals that pose the greatest risk to the public and the environment. This regulation will require the preparation of risk management plans for listed regulated chemicals at LANL by June 1999, and within 3 years after listing any new regulated chemical.

On July 18, 1997, the EPA adopted a new National Ambient Air Quality Standard (NAAQS) for particulate matter (PM) with a diameter less than or equal to 2.5 micrometers ($PM_{2.5}$), and reference methods for determining attainment with the standard. Also on July 18, 1997, EPA revised the NAAQS and associated reference method for determining ozone attainment. Both standards will be incorporated into the SIP for New Mexico and be applicable to LANL. Determination of attainment of both standards is based on a reference method utilizing 3-year averaging.

In addition to the existing federal programs, the *Clean Air Act Amendments of 1990* mandate new programs that may affect future LANL programs. These programs require technology for controlling hazardous air pollutants and replacing chlorofluorocarbons. Regulations are still being developed to implement these aspects of the act.

7.4.2 *New Mexico Air Quality Control Act*

Nonradioactive air emissions from LANL facilities are subject to the regulatory requirements established under the *New Mexico Air Quality Control Act* (sections 74-2-1 *et seq.*, NMSA 1978). The New Mexico Environmental Improvement Board, as provided by the *New Mexico Air Quality Control Act*, regulates air quality through a series of air quality control regulations in NMAC. These regulations are administered by NMED. NMAC provides emission standards for emission sources and processes such as open burning, boilers, and asphalt plants. Some of the main regulations relevant to LANL operations are discussed below.

7.4.2.1 *Construction Permits*

Provisions of 20 NMAC 2.72 require construction permits for any new or modified source of any regulated air contaminant if they exceed threshold emission rates. More than 500 toxic air pollutants are regulated, and each chemical's threshold hourly rate is based on its toxicity. Each new or modified air emission source is reviewed, and conservative estimates are made of maximum hourly chemical use and emissions. These estimates are compared with the applicable 20 NMAC 2.72 limits to determine whether additional permits are required.

7.4.2.2 *Operating Permits*

On July 21, 1992, EPA promulgated 40 CFR 70, O*perating Permit Program*, which implements Title V of the CAA. The purpose of this program is to: (1) identify all the air quality regulations and emission limitations applicable to an air pollution source; and (2) establish monitoring, record keeping, and reporting requirements necessary to demonstrate continued compliance with these requirements. This regulation required each state to develop an operating permit program meeting the minimum requirements set forth in 40 CFR 70 and submit their program to EPA for review by November 1993. The NMED Operating Permit Program established under 20 NMAC 2.70 was approved by EPA in December 1994. It requires that all major producers of air pollution obtain an operating permit from NMED. Due to LANL's potential to emit large quantities of regulated air pollutants (nitrogen oxides and carbon monoxide—primarily from steam plants), LANL is considered a major source.

In accordance with 20 NMAC 2.70, LANL submitted an operating permit application to NMED in December 1995. NMED has issued a Notice of Completeness for the application but has not yet issued an operating permit.

7.4.2.3 *Prevention of Significant Deterioration*

This regulation (20 NMAC 2.74) has stringent requirements that must be addressed before construction of any new, large stationary source can begin. Under 20 NMAC 2.74, wilderness areas, national parks, and national monuments receive special protection; thus, the proximity of Bandelier National Monument's (BNM) Wilderness Area could have an impact on any proposed new construction at LANL. All of the new or modified air emission sources at LANL are reviewed for compliance with the requirements of 20 NMAC 2.74. Because the total emissions of any criteria pollutant from LANL are below the regulation's threshold of 250 tons a year, currently this regulation does not apply to LANL.

7.4.2.4 *Emission Standards for Hazardous Air Pollutants*

In its regulation governing emission standards for HAPs (20 NMAC 2.78), NMED has adopted by reference all of the federal NESHAP provisions, except those for radionuclides. The only two nonradionuclide NESHAP provisions applicable to LANL are those for asbestos and beryllium.

Under NESHAP for asbestos, LANL is required to notify NMED of asbestos removal operations and disposal quantities and to ensure that these operations produce no visible emissions. Asbestos removal activities involving less than 160 square feet (15 square meters) are covered by an annual small-job notification to NMED. Projects involving greater amounts of asbestos require separate advance notification to NMED. Quantities of asbestos wastes for both small and large jobs are reported to NMED on a quarterly basis. These reports include any asbestos contaminated, or potentially contaminated, materials with radionuclides. Radioactivity contaminated material is disposed of in a designated radioactive asbestos burial area. Nonradioactive asbestos is transported off the site to designated commercial asbestos disposal areas.

The beryllium NESHAP includes requirements for preconstruction and preoperation approval of beryllium machining operations and for start-up testing of stack emissions from these operations. Before the beryllium NESHAP became applicable for DOE operations in the mid 1980's, NMED, DOE, and LANL agreed to follow the NMED new-source preconstruction/ preoperation approval process for large, existing beryllium-machining operations at LANL. Since then, several very small beryllium machining operations that were already in existence have been registered with NMED.

7.4.3 *Noise Control Act of 1972*

By the *Noise Control Act of 1972* (42 U.S.C. §4901), Congress directed all federal agencies to carry out the programs under their control to promote an environment free from noise that jeopardizes public health or welfare. Furthermore, it requires any federal agency engaged in any activity resulting, or which may result, in the emission of noise, to comply with federal, state, interstate, and local requirements respecting control and abatement of environmental noise to the same extent that any person is subject to such requirements. Beyond the general obligation in the act and implementing regulations, there are no specific federal requirements regulating environmental noise, nor are there state requirements. Noise exposures to occupational workers are regulated under OSHA, and for DOE contractors through an equivalent program implemented by DOE orders. The Los Alamos County Code (Chapter 8.28) does have noise restrictions, with identified permissible noise levels for residential areas during specified times. Permits can be requested for exceedances for noise generating activities of a temporary nature.

7.5 WATER RESOURCES

7.5.1 *Clean Water Act*, as Amended

The *Clean Water Act* (33 U.S.C. §1251) has a goal to "restore and maintain the chemical, physical and biological integrity of the nation's waters," including to "provide for the protection and propagation of fish, shellfish, and wildlife." The regulations that implement the *Clean Water Act* contain limitations and permitting requirements for discharges of pollutants from point sources; disposal of dredged or fill material at wetlands and other waters of the U.S.; stormwater discharges from construction and industrial runoff; and oil discharges. Key elements of the act include: (1) nationally applicable, technology-based effluent limitations set by EPA for specific industry categories; and (2) water quality standards set by states.

EPA is the regulating authority for point source and stormwater discharge permits in New Mexico. Permits are issued and enforced by EPA Region 6 in Dallas, Texas. New Mexico does not have a state point source discharge permit program. However, NMED performs some compliance evaluation inspections and monitoring for EPA through a water quality grant issued under Section 106 of the act. The U.S. Army Corps of Engineers administers the dredged or fill material permit program (Section 404) of the *Clean Water Act*. LANL submits applications as necessary for disposal of dredged and fill material under Section 404 for construction activities. The *New Mexico Groundwater Protection Act* (74-6B-1 *et seq.*, NMSA 1978), *Water Quality Act* (74-6-1 *et seq.*, NMSA 1978) and implementing regulations establish state standards for protection of surface and groundwater resources that are also applicable to LANL activities.

7.5.1.1 *National Pollutant Discharge Elimination System Permit Program/ Liquid Radioactive Discharges*

The *Clean Water Act* contains provisions for the National Pollutant Discharge Elimination System (NPDES), a permitting program for the discharge of pollutants from any point source into waters of the U.S. Individual NPDES permits set limitations for specified pollutants at specific outfalls.

LANL has operated under three primary NPDES permits. UC and DOE are co-operators on a site-wide NPDES permit (EPA 1994) issued by EPA Region 6 and effective August 1, 1994, covering the industrial and sanitary effluent discharges at Los Alamos. Industrial discharges from the hot dry rock geothermal facility, Fenton Hill (Technical Area [TA]–57), are permitted separately (EPA 1979). This permit was canceled as of December 1997. A General Permit for storm water associated with industrial activity (EPA 1992) was also issued in September 1992. These permits regulate all routine effluent discharges at LANL. Storm water discharges associated with facility construction or environmental restoration activities are also authorized through the applicable NPDES program. Then they are included in the General Industrial Storm Water Permit or terminated as applicable. The number of NPDES General Permits for construction storm water discharges varies, with usually five to eight in effect at one time.

During the early 1990's, LANL was listed as a "Significant Non-Compliant Federal Facility" by EPA Region 6 for NPDES violations. DOE and LANL have had several Federal Facility Compliance Agreements and parallel administrative orders in effect to correct NPDES deficiencies. The current DOE compliance agreement (Docket No. VI–96–1237, December 12, 1996) (EPA 1996b) and the current LANL administrative order (AO Docket No. VI–96–1236, December 10, 1996) (EPA 1996c) include schedules for coming into full compliance with the *Clean Water Act* by completing the High Explosives Wastewater Treatment Facility (HEWTF) and Waste Stream Characterization projects. These corrective actions required by the compliance agreement and the administrative order are continuing.

Although maintaining a 98 to 99 percent compliance rate with required permit limitations, LANL has had, and continues to have, chronic problems meeting NPDES industrial/sanitary permit conditions. Exceedances are self reported under the conditions of the permit, and have consisted of occasional exceedances at some outfalls of arsenic, chlorine, total suspended solids, hydrogen-ion concentration, chemical oxygen demand, biological oxygen demand, cyanide, vanadium, copper, iron, oil and grease, silver, phosphorus, and radium. The total number of exceedances for calendar years 1991 through 1996 are shown in Figure 7.5.1.1–1.

LANL actions to improve compliance with permit conditions are continually being taken including, elimination of outfalls, improvements and corrective actions at specific outfalls, and implementation of the Waste Stream Characterization Program and Corrections Project.

Radioactive liquid effluent discharges are regulated by DOE Order 5400.5. One NPDES permitted outfall at TA–50, the Radioactive Liquid Waste Treatment Facility, began operations in 1963. This outfall has continued to discharge residual radionuclides to Mortandad Canyon in liquid effluents to the present time. DOE Order 5400.5 specifies DCGs for liquid radioactive effluents, which provide a reference for determining dose to various exposure pathways. For liquid radioactive effluents, the "as low as reasonably achievable" (ALARA) and "best available

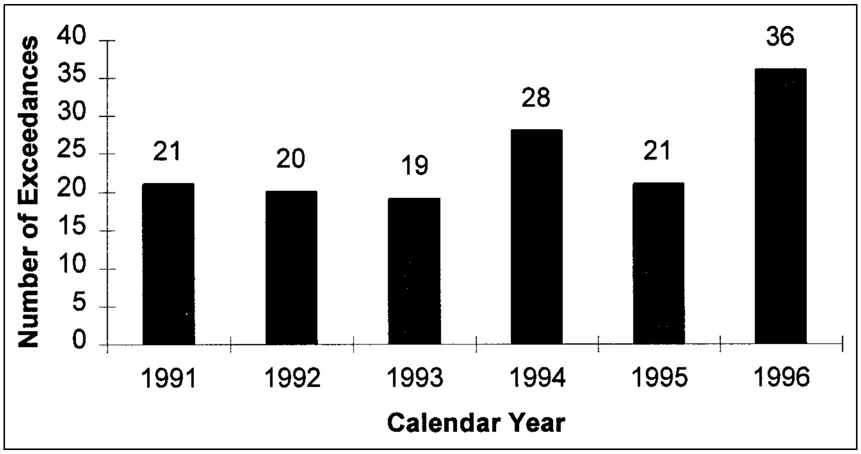

FIGURE 7.5.1.1–1.—*National Pollutant Discharge Elimination System Permit Exceedances.*

technology" (BAT) processes are adopted to determine the appropriate level of treatment. If discharges are below the DCG reference values at the point of discharge to a surface waterway, generally no further treatment is required due to cost/benefit considerations. Historic discharges to Mortandad Canyon have resulted in above background residual radionuclide concentrations in alluvial groundwater and sediments. For calendar year 1996, two DCGs were exceeded in TA–50 effluents (for americium-241 and plutonium-238). The TA–50 discharge also contains nitrates that have caused the alluvial groundwater to exceed the state groundwater standard of 10 milligrams per liter. LANL is working to continue to upgrade the treatment process at TA–50 to correct these problems. Investigation and cleanup, if required, are conducted through the Environmental Restoration Project, and interim controls (sediment traps) have been implemented to control movement of contaminants off the site.

7.5.1.2 *Unplanned Discharges, Spills, and Releases*

LANL also has had continuing problems with unplanned liquid discharges, or spills of water contaminants, which are required to be reported to NMED as unpermitted discharges to surface water or groundwater under the New Mexico Water Quality Control Commission (NMWQCC) regulations. Primarily, these have consisted of unpermitted or unplanned releases of potable water, wastewater or sewage, cooling water, and steam condensate from line breaks and overflows, with occasional reportable small quantity releases of mineral oil, gasoline, diesel oil, hydraulic oil, ethylene glycol, and other liquids. Some discharges of oil are also reportable to the National Response Center pursuant to 40 CFR 110.6. Spills and releases are reported in accordance with regulations, and cleanup is conducted by LANL as necessary. NMED administratively reviews and closes actions taken on reported spills as staff and time permits. The total number of liquid spills reportable to NMED for the period 1991 through 1996 are shown in Figure 7.5.1.1–2.

LANL has had six releases involving spills, leaks, or seepage of water with low levels of radioactive contamination in the period 1991 through 1996. These are evaluated and cleaned up if necessary in accordance with DOE Order 5400.5 criteria.

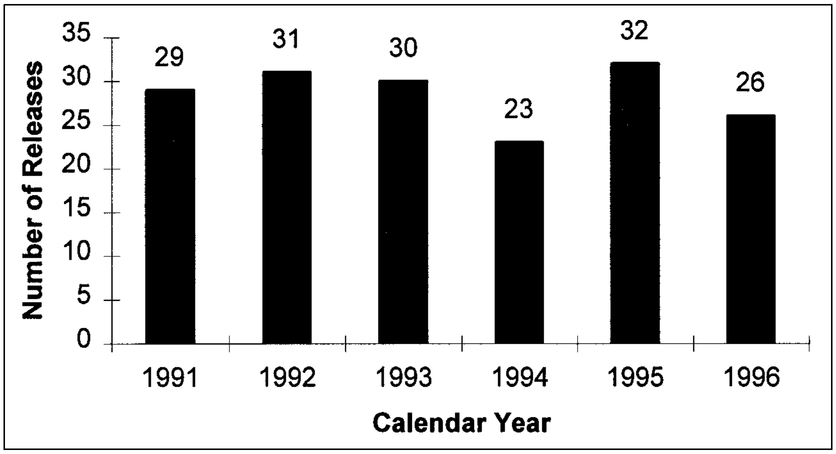

FIGURE 7.5.1.1–2.—*Liquid Release Notifications.*

7.5.1.3 *Spill Prevention Control and Countermeasure Plan*

LANL has a spill control and countermeasure plan for oil spills (LANL 1997), as required by 40 CFR 112 under the *Clean Water Act*. This plan requires that secondary containment be provided for all aboveground storage tanks containing oil. The plan also provides for spill control at oil storage sites at LANL. This plan meets requirements of both EPA and NMED for control of spills to surface areas and below the ground surface.

7.5.1.4 *Sanitary Sewage Sludge Management Program*

In December 1992, EPA promulgated 40 CFR 503, *Standards for Use or Disposal of Sewage Sludge*. The purpose of these regulations is to establish numerical, management, and operational standards for the beneficial use or disposal of sewage sludge through land application or surface disposal. Under the Part 503 regulations, LANL is required to collect representative samples of sewage sludge to demonstrate that it is not a hazardous waste and that it meets the minimum federal standards for pollutant concentrations. In 1996, analytical sampling demonstrated 100 percent compliance with land application standards. However, low levels of polychlorinated biphenyls (PCBs) detected in the sludge have caused LANL to suspend land application of sludge, in preference to other disposal options. All sewage sludge generated at the TA–46 Sewage Treatment Plant is now handled as PCB-contaminated waste and disposed of off the site rather than by land application.

7.5.1.5 *Safe Drinking Water Act, as Amended*

The *Safe Drinking Water Act* (SDWA) (42 U.S.C. §300f) sets national standards for contaminant levels in public drinking water systems, regulates the use of underground injection wells, and prescribes standards for groundwater aquifers that are a sole source of drinking water. Primary enforcement responsibility for the act is by the states. EPA has given NMED authority to administer and enforce federal drinking water regulations and standards in New Mexico. This act authorizes regulations that establish national drinking water standards for contaminants in public drinking water systems. The implementing regulations are found in *National Interim*

Primary Drinking Water Regulations. The regulations also set maximum contaminant level goals (40 CFR 142) and secondary standards to control contaminants in drinking water that primarily affect aesthetic qualities related to public acceptance of drinking water (40 CFR 143). These standards have been adopted by New Mexico and are included in the *New Mexico Drinking Water Regulations*. The state has issued regulations containing maximum contaminant levels (MCLs) and standards for radioactive contamination (20 NMAC 7.1). EPA maintains oversight responsibilities over the states, sets new contaminant standards as appropriate, and maintains separate enforcement responsibility for the Underground Injection Control Program.

The SDWA applies to federal facilities that own or operate a public water system. A "public water system" means a system for the provision of piped water for human consumption that has at least 15 service connections or regularly serves at least 25 individuals. DOE provides drinking water to LANL, Los Alamos County, and BNM. LANL, as operator of the water system, is required to monitor drinking water quality for organic and inorganic compounds, radionuclides, metals, and coliforms. LANL has established a sampling program for ensuring SDWA compliance.

7.5.1.6 *Groundwater Protection Requirements*

There are numerous federal, state, and DOE requirements related to groundwater protection and management. The State of New Mexico protects groundwater via the NMWQCC regulations, which control discharges of water contaminants onto or below the ground surface to protect all groundwater of the State of New Mexico. Under these regulations, a groundwater discharge plan may be required to be submitted to and approved by NMED for a discharging facility (or by the Oil Conservation Division for energy/mineral extraction activities). Subsequent discharges must comply with the terms and conditions of the discharge plan. In 1997, LANL had three Groundwater Discharge Plans in effect. The NMWQCC regulations were significantly expanded in 1995 with the adoption of comprehensive abatement regulations. The purpose of these regulations is to abate both surface and subsurface contamination for designated or future uses. Of particular importance to DOE and LANL is the contamination that may be present in alluvial groundwater.

Groundwater monitoring and protection requirements are also included in DOE Order 5400.1, *General Environmental Protection Program*. The order requires LANL to prepare a Groundwater Protection Management Program Plan (GWPMPP) and to implement the program outlined by that plan. The GWPMPP also fulfills the requirements of Chapter IV, Section 9, of DOE Order 5400.1, which requires development of a groundwater monitoring plan. The groundwater monitoring plan identifies all DOE requirements and regulations applicable to groundwater protection and includes strategies for sampling, analysis, and data management. LANL's GWPMPP was most recently approved by DOE on March 15, 1996 (LANL 1996).

Section 9c of Chapter IV of DOE Order 5400.1 requires that groundwater monitoring needs be determined by site-specific characteristics and, where appropriate, that groundwater monitoring programs be designed and implemented in accordance with RCRA regulations 40 CFR 264, Subpart F, or 40 CFR 265, Subpart F. The section also requires that monitoring for radionuclides be in accordance with DOE Order 5400.5, *Radiation Protection of the Public and the Environment.*

In addition to DOE Order 5400.1, Module VIII of the LANL RCRA permit requires LANL to collect information to supplement and verify existing information on the environmental setting at the facility and collect analytical data on groundwater contamination. Under Task III, Section A.1, LANL is required to conduct a program to evaluate hydrogeological conditions. Under Task III, Section C.1, LANL is required to conduct a groundwater investigation to characterize any plumes of contamination at the facility.

Historically, the groundwater monitoring requirements of RCRA (40 CFR 264 Subpart F) have not been applied to LANL's regulated hazardous waste management units (treatment, storage, and disposal) because DOE and LANL had submitted groundwater monitoring waiver demonstrations based on the depth to groundwater and lack of physical evidence of contaminant migration to these depths. However, on May 30, 1995, NMED denied DOE/LANL groundwater monitoring waiver demonstrations, and groundwater monitoring program plans were requested for DOE/LANL to bring the laboratory into compliance with RCRA. In the denial letter, NMED recommended the development of a comprehensive groundwater monitoring program plan that addresses both site-specific and LANL-wide groundwater monitoring objectives. This was in part satisfied with submittal of a revised GWPMPP in 1995. In an August 17, 1995, letter, NMED again expressed concerns over groundwater protection, listed four unresolved issues, and requested a RCRA Hydrogeologic Workplan. On December 6, 1996, a draft Hydrogeologic Workplan was submitted to NMED addressing these unresolved issues. LANL is currently implementing actions defined in the Hydrogeologic Workplan. The Hydrogeologic Workplan was approved by NMED March 1998 and revised by LANL May 1998 (LANL 1998).

7.6 LAND RESOURCES (WASTE MANAGEMENT, TOXIC SUBSTANCES, POLLUTION PREVENTION, AND ENVIRONMENTAL RESTORATION)

Federal facilities are subject to a variety of federal and state environmental statutes and implementing regulations related to waste management, prevention of pollution, and environmental cleanup. These requirements are primarily oriented toward prevention of pollution of land resources, and cleanup of past spills and releases. These include the RCRA; the *Federal Facility Compliance Act*; the *Toxic Substances Control Act* (TSCA); the *Federal Insecticide, Fungicide, and Rodenticide Act* (FIFRA); and the CERCLA. These acts address the management of waste and hazardous substances, and the release or threat of release of hazardous substances, primarily to soil and groundwater. The *Hazardous Material Transportation Act* is also included, which governs the transportation of hazardous materials and waste.

7.6.1 *Resource Conservation and Recovery Act*

The RCRA (42 U.S.C. §6901 *et seq.*) regulates the management of solid waste. Solid waste is broadly defined to include any garbage, refuse, sludge, or other discarded material including solid, liquid, semisolid, or contained gaseous materials resulting from industrial, commercial, mining, or agricultural activities. Specifically excluded as solid waste is source, special nuclear, or byproduct material as defined by AEA. Nonhazardous solid waste is regulated under subtitle D of RCRA, the *New Mexico Solid Waste Act* (NMSWA) (74-9-1 *et seq.*, NMSA 1978), and its implementing regulations, the New Mexico Solid Waste Management Regulations (20 NMAC 9). New Mexico has primary regulatory authority. The state does not have authority to regulate the management and disposal of radioactive waste from DOE facilities operated under AEA.

LANL maintains an industrial solid waste landfill at Area J of TA–54 (on Mesita del Buey), which is subject to and operates under New Mexico's Solid Waste Management Regulations (20 NMAC 9.1). The landfill is used as a disposal site for solid wastes (such as classified wastes, other nonhazardous waste materials, and "special solid waste" as defined by the State of New Mexico) and as a staging area for nonradioactive asbestos waste, which is later shipped off the site to an approved commercial disposal facility. Radioactive asbestos waste and asbestos waste suspected of being contaminated with radioactive material (excluded as solid wastes under the New Mexico regulations) are disposed in a dedicated cell constructed at TA–54, Area G.

LANL disposes of most sanitary solid waste and rubble at the Los Alamos County Landfill and an adjacent rubble pile on East Jemez Road. This landfill lies on DOE property, but is owned and operated by Los Alamos County under a special-use permit (an agreement between DOE's Los Alamos Area Office and the county specifies the types of wastes that may be disposed of in the landfill). LANL contributes about one-third of the total volume of wastes entering this landfill. As the owner and operator, Los Alamos County is responsible for day-to-day operational compliance and obtaining necessary permits from the state under 20 NMAC 9.1.

In 1976, RCRA established requirements and procedures for the management of hazardous wastes. As amended by the *Hazardous and Solid Waste Amendments of 1984* (HSWA), RCRA Subtitle C defines hazardous wastes that are subject to regulation and sets standards for generation of waste and for treatment, storage, and disposal facilities. The HSWA emphasizes reducing the volume and toxicity of hazardous waste. The RCRA and HSWA also establish permitting and corrective action (i.e., cleanup) requirements for RCRA-regulated hazardous waste facilities.

Original jurisdiction for implementing hazardous waste management aspects of the RCRA was with the EPA; however, the RCRA authorizes EPA to delegate responsibility to individual states as they develop satisfactory implementation programs. EPA granted base RCRA authorization to New Mexico on January 25, 1985, transferring regulatory authority over hazardous wastes under the RCRA to NMED. State authority for hazardous waste regulation is set forth in the *New Mexico Hazardous Waste Act* and Hazardous Waste Management Regulations (20 NMAC 4.1), which adopt, with a few minor exceptions, all of the federal regulations in effect. On July 25, 1990, the State of New Mexico's Hazardous Waste Program was authorized by EPA to regulate mixed waste in lieu of the federal program.

On November 8, 1989, DOE and UC, as co-operators of LANL, were granted a RCRA operating permit, which establishes requirements for hazardous waste management units. A Part A application for mixed waste storage and treatment units throughout LANL was submitted on January 25, 1991. Permit modifications and additional revised Part A and Part B applications have been submitted since 1991 for mixed waste units. All existing mixed waste units are operating either under permit or interim status pending permit issuance.

DOE and EPA signed a Federal Facility Compliance Agreement on March 15, 1994, addressing identified noncompliances with stored mixed waste treatment requirements under the land disposal restrictions (LDRs). This compliance agreement was terminated with issuance by the State of New Mexico of a *Federal Facility Compliance Order* in October 1995 under the *Federal Facility Compliance Act*, which addresses treatment schedules for mixed waste to meet LDR standards.

LANL has received a number of compliance orders issued by NMED for noncompliances with hazardous waste management requirements. DOE and LANL are subject to a three-party consent agreement for compliance orders issued by NMED in 1993 regarding corrective actions that resolved the Transuranic Waste Inspectable Storage Project (TWISP) at TA–54, Area G (NMED 1993). This project involves the recovery of transuranic (TRU) and TRU-mixed waste containers stored on earthen covered pads at TA–54, Area G, and placement of that waste into compliant inspectable storage. The deadline for completion of this project is September 2003.

LANL also is currently subject to an Amended Stipulations, dated May 23, 1995, that is part of a settlement reached in response to Compliance Order NMHWA 94-09 (NMED 1995a). The Amended Stipulation requires LANL to exercise due diligence in addressing and working off 644 gas cylinders that had exceeded the allowable 1-year storage limit for land disposal restriction. All but four of the gas cylinders have been dealt with under the terms of the Amended Stipulation. Until these four cylinders meet the terms of the Amended Stipulation, LANL will continue to submit quarterly progress reports, as required by the Amended Stipulation, to demonstrate due diligence in working off the cylinders. All other compliance orders relating to hazardous waste activities have been closed.

The HSWA (1984) modified the hazardous waste permitting sections of the RCRA (Sections 3004 and 3005). In accordance with these provisions, LANL's permit to operate includes a section (HSWA Module VIII) that prescribes a specific corrective action program for LANL, the primary focus of which is the investigation and cleanup, if required, of inactive sites called solid waste management units (SWMUs). The HSWA Module specifies the corrective action process, which is being implemented at LANL by the Environmental Restoration Project.

The corrective action process at LANL consists of: (1) preparing RCRA facility investigations to identify the extent of contamination in the environment and the pathways along which these contaminants could travel to human and environmental receptors; (2) preparing corrective measures studies if needed to evaluate alternative remedies for reducing risks to human and environmental health and safety in a cost-effective manner; and (3) corrective measures implementation—the remedy chosen is implemented, its effectiveness is verified, and ongoing control and monitoring requirements are established.

7.6.2 Radioactive Waste Management Requirements

Low-level radioactive waste (LLW) is a waste that contains radioactivity and is not classified as high-level radioactive waste, TRU waste, or spent nuclear fuel. Solid LLW usually consists of clothing, tools, and glassware. Low-level radioactive liquid waste consists primarily of water circulated as cooling water. Radioactive waste management at LANL is regulated under the AEA, through applicable DOE orders (primarily DOE Order 5820.2A, *Radioactive Waste Management*, and DOE Order 5400.5, *Radiation Protection of the Public and the Environment*). DOE Order 5400.5 also provides criteria and processes for the release of materials (through sale or disposal) to assure that released materials do not constitute a hazard to the public and the environment due to their radioactive content. This includes materials that are not waste. LANL has reported and taken corrective action for a number of incidents involving the inadvertent release of contaminated materials not releasable under the criteria in DOE Order 5400.5. During the period 1991 through 1996, these incidents have usually consisted of the discovery of contaminated equipment at salvage yards or in other uncontrolled locations, and in two reported incidents at the Los Alamos County Landfill. When incidents are discovered, actions are taken to immediately control the material as radioactive contaminated, and it is removed to a controlled area or decontaminated in accordance with DOE radiation control requirements.

Low-level radioactive mixed waste (LLMW) is waste containing both hazardous and low-level radioactive components. As a hazardous waste, mixed waste is regulated under the RCRA and New Mexico hazardous waste management regulations. Because it is radioactive, the radioactive component is also regulated under the AEA through applicable DOE orders. LLMW is disposed of at off-site facilities.

Due to the nationwide lack of DOE treatment capacity and capability for mixed waste, LANL has continued to store many mixed wastes on the site. On March 15, 1994, DOE and EPA signed a Federal Facility Compliance Agreement to address compliance with the storage prohibitions for mixed waste at LANL. This agreement was terminated with the issuance of the Federal Facility Compliance Order in October 1995 with NMED implementing the Site Treatment Plan for LANL, under provisions of the *Federal Facility Compliance Act*.

TRU waste, regardless of form or source, is contaminated with alpha-emitting transuranium radionuclides with half-lives greater than 20 years and concentrations greater than or equal to 100 nanocuries per gram at the time of assay. TRU waste at LANL is scheduled to be sent to the WIPP when that facility opens. TRU waste is subject to the waste acceptance criteria (WAC) for WIPP, DOT shipping requirements, and applicable DOE orders dealing with its safe handling and management.

7.6.3 *Federal Facility Compliance Act*

The *Federal Facility Compliance Act* (Public Law [PL] 102–386, 106 Stat. 1505), enacted in 1992, amended RCRA and waives sovereign immunity from fines and penalties for RCRA violations at federal facilities. However, the act postponed the waiver for 3 years for storage prohibition violations with regard to land disposal restrictions for DOE's mixed wastes. It also required DOE to prepare plans for developing the required treatment capacity for its mixed waste for each site at which it stores or generates mixed waste. Each plan (referred to as a site treatment plan) must be approved by the state or EPA after consultation with other affected states, consideration of public comments, and issuance of an order by the regulatory agency requiring compliance with the plan. The act further provides that DOE will not be subject to fines and penalties for storage prohibition violations for mixed waste as long as it is in compliance with an existing agreement, order, or permit.

The *Federal Facility Compliance Act* requires that site treatment plans contain schedules for developing treatment capacity for mixed waste for which identified technologies exist. For mixed waste without an identified existing treatment technology, DOE must provide schedules for identifying and developing technologies.

LANL has submitted site treatment plans to NMED to address the development of new treatment capabilities in compliance with the act. A Federal Facility Compliance Order was issued on October 4, 1995, to address treatment schedules for mixed waste (NMED 1995b). The Mixed Waste Land Disposal Restriction Federal Facility Compliance Agreement with EPA of March 15, 1994, was terminated with this new agreement.

7.6.4 Underground Storage Tanks, RCRA Subtitle I

Underground storage tanks (USTs) containing petroleum or hazardous substances are regulated as a separate program under Subtitle I of the RCRA, which establishes regulatory requirements for USTs containing hazardous or petroleum materials. NMED has been delegated authority for regulating USTs under the New Mexico Underground Storage Tank Regulations, which implement the *New Mexico Hazardous Waste Act* and the *New Mexico Groundwater Protection Act*. These regulations include requirements for: (1) design, construction, and installation of new tanks; (2) maintenance of a leak detection system and associated record keeping; (3) reporting of hazardous or petroleum releases; (4) corrective action in the event of a release; and (5) closure of UST systems. All existing tank systems must either meet new tank performance standards or undergo closure by December 22, 1998. All LANL USTs will be upgraded or undergo closure by the December 22, 1998 deadline. LANL complied with the deadline for upgrading, replacing, or properly closing all USTs at LANL.

7.6.5 *Comprehensive Environmental Response, Compensation, and Liability Act*, as Amended

CERCLA (PL 96-510) (42 U.S.C. §9601 *et seq.*), as amended by *Superfund Amendments and Reauthorization Act* (SARA) of 1986 (PL 99-499), provides for liability, compensation, cleanup, and emergency response for hazardous substances released into the environment and cleanup of inactive hazardous substances disposal sites. The CERCLA also established a fund that is financed by hazardous waste generators and is used to financially support clean-up and response actions of abandoned hazardous waste sites when no financially responsible party(ies) can be found. Parties responsible for the contamination of sites are liable for all costs incurred in the clean-up and remediation process. EPA is the regulating authority for the act. Some applicable implementing regulations are contained in the *National Oil and Hazardous Substances Pollution Contingency Plan* (40 CFR 300), and *Designation, Reportable Quantities, and Notification* (40 CFR 302).

LANL has been evaluated and did not score high enough to be placed on the National Priority List for past releases into the environment. Therefore, all legacy contamination found in the environment at LANL is primarily cleaned up under RCRA corrective action authority (HSWA Permit Module VIII). Executive Order 12580, which applies to facilities that are not on the National Priorities List, delegates responsibility to the heads of executive departments and agencies at those facilities for undertaking remedial and removal actions for releases or threatened releases. This authority applies to any clean-up actions not included as a RCRA corrective action.

The CERCLA was amended by the SARA in 1986. The SARA Title III establishes additional requirements for emergency planning and reporting of hazardous substance releases. The SARA Title III is also known as the *Emergency Planning and Community Right-to-Know Act* (EPCRA), which, due to its unique requirements, is discussed separately below. The SARA also created liability for damages to or loss of natural resources resulting from releases into the environment, and required the designation of federal and state officials to act as public trustees for natural resources. The *New Mexico Natural Resources Trustee Act* (75-7-1 *et seq.*, NMSA 1978) is the state statute designed to protect state natural resources. DOE, as the federal trustee, and the State of New Mexico have authority to act as trustees for most resources at LANL. The DOI retains authority for certain designated sensitive natural resources. Other natural resource trustees act for lands surrounding LANL, including the Pueblo tribes. Procedures for conducting natural resource damage assessments are codified at 43 CFR 11. A strategy and plan for integrating the natural resource damage assessment requirements into the HSWA corrective action (environmental restoration) process at LANL is being developed.

LANL is subject to and required to report releases to the environment under the notification requirements in 40 CFR 302. In the period 1991 through 1996, LANL has had four releases to the environment exceeding a reportable quantity in 40 CFR 302.4. One was a planned release by remote detonation of an overpacked chlorine cylinder on May 18, 1993, resulting in the release of a maximum of 100 pounds of chlorine under controlled conditions. Another was a stack release of tritium exceeding 100 curies on January 25, 1994, at TA–33. Two additional reportable releases involved the release of a water/ethylene glycol mixture (coolant) in excess of 1 pound on June 18, 1993 and June 22, 1993.

7.6.6 *Toxic Substances Control Act*

The TSCA (15 U.S.C. §2601 *et seq.*) is administered by EPA. Unlike other statutes that regulate chemicals and their risk after they have been introduced into the environment, the TSCA was intended to require testing and risk assessment before a chemical is introduced into commerce. The TSCA also establishes record-keeping and reporting requirements for new information regarding adverse health and environmental effects of chemicals. The TSCA also governs the manufacture, use, storage, handling, and disposal of PCBs; sets standards for cleaning up PCB spills; and establishes standards and requirements for asbestos identification and abatement in schools.

Because LANL's research and development activities are not usually related to the manufacture of new chemicals, PCB regulations (40 CFR 761) are LANL's main concern under the TSCA. Activities at LANL that are governed by PCB regulations include, but are not limited to, management and use of authorized PCB-containing equipment, such as transformers and capacitors; management and disposal of substances containing PCBs (dielectric fluids, contaminated solvents, oils, waste oils, heat transfer fluids, hydraulic fluids, paints, slurries, dredge spoils, and soils); and management and disposal of materials or equipment contaminated with PCBs as a result of spills.

The TSCA regulates PCB items and materials having concentrations exceeding 50 parts per million. The regulations contain an antidilution clause that requires waste to be managed based on the PCB concentration of the source (transformer, capacitor, PCB equipment, etc.), regardless of the actual concentration in the waste. If the concentration at the source is unknown, the waste must be managed as though it were a spill of mineral oil with an assumed PCB concentration of 50 to 500 parts per million. At LANL, PCB-contaminated wastes are transported off the site for treatment and disposal unless they also have a radioactive component. Wastes in solid form containing both radionuclides and PCBs are disposed at Area G (TA–54), which has been approved by EPA for such disposal (provided that strict requirements are met with respect to notification, reporting, record keeping, operating conditions, environmental monitoring, packaging, and types of wastes disposed).

LANL has reported four small spills (0.34 fluid ounces [10 milliliters] to 0.5 gallons [1.9 liters]) involving PCB-contaminated materials during the period 1991 through 1996. None of these spills exceeded CERCLA reportable quantities, and they were cleaned up using the policy and guidelines in 40 CFR 761.

LANL currently has no treatment or disposal facilities for liquid wastes that contain both radionuclides and PCBs. Such wastes have been stored at Area L at TA–54 for longer than 1 year (in violation of TSCA regulations that stipulate a maximum of 1 year for “storage for disposal” of PCBs). However, commercial facilities do not exist to accept these wastes because of the radionuclide component. In August 1996, EPA and DOE signed a national Federal Facility Compliance Agreement allowing long-term storage of these radioactive liquid wastes containing PCBs, and establishing requirements for DOE to meet in the interim (EPA 1996d).

The asbestos abatement regulations of the TSCA (40 CFR 763) relate primarily to the identification and abatement of asbestos containing materials in schools. LANL conducts asbestos abatement projects in accordance with OSHA requirements (29 CFR 1926), and applicable requirements of the CAA NESHAP 40 CFR 61, Subpart M for notification and waste management/disposal, and the New Mexico Solid Waste Management Regulations.

7.6.7 *Hazardous Materials Transportation Act*

This act defines the requirements of DOT applicable to the packaging and transportation of hazardous materials. The regulations list and classify the materials that DOT (the regulating authority) has designated as “hazardous.”

Implementing regulations include *General Information, Regulations, and Definitions* (49 CFR 171); *Hazardous Materials Tables, Special Provisions, Hazardous Materials Communications, Emergency Response Information, and Training Requirements* (49 CFR 172); *General Requirements for Shipments and Packaging*s (49 CFR 173); *Carriage by Rail* (49 CFR 174); *Carriage by Public Highway* (49 CFR 177); and *Specifications for Packagings* (49 CFR 178). Specific packaging requirements for radioactive materials are in 49 CFR 173, Subpart I. The requirements prescribed in Subpart I are in addition to, not in place of, requirements of the NRC set forth in 10 CFR 71.

DOE must comply with the *Hazardous Materials Transportation Act* (49 U.S.C. §801 *et seq.*) and implementing regulations, and with specific facility WAC when packaging and transporting waste destined for WIPP and other off-site federal or commercial facilities. LANL must also meet applicable manifesting requirements for shipping hazardous materials such as preparing shipping papers, marking and labeling packages, and placarding transport vehicles as outlined in the act and implementing regulations. Because LANL consists of many separate TAs connected in many instances by public roads, inter-TA transportation requirements must consider applicable packaging and transportation requirements for the movement of hazardous materials within LANL as well. This may include meeting the transportation requirements fully, or utilizing road closures or other means to maintain compliance with the regulations. The state agency regulating transportation of hazardous materials is the Motor Transportation Division of the New Mexico Tax and Revenue Department (65-3-13, NMSA 1978). New Mexico has adopted by reference the hazardous materials transportation regulations promulgated by DOT.

7.6.8 *Federal Insecticide, Fungicide, and Rodenticide Act*

This act regulates the use, registration, and disposal of several classes of pesticides. In order to ensure that pesticides are applied in a manner that protects the applicators, workers, and the environment, LANL must meet requirements of the FIFRA (7 U.S.C. §136 *et seq.*). Implementing regulations include recommended procedures for the disposal and storage of pesticides (40 CFR 165 [proposed regulation]) and worker protection standards (40 CFR 170). EPA is the regulating authority for LANL. LANL is also regulated by the *New Mexico Pest Control Act*, administered by the Board of Regents of New Mexico State University. The LANL Pest Control Management Plan, which includes programs for vegetation, insects, and small animals, was established in 1984 and is revised as necessary.

7.6.9 *Pollution Prevention Act of 1990*

The *Pollution Prevention Act of 1990* (42 U.S.C. §13101 *et seq.*) sets the national policy for waste management and pollution control that focuses first on source reduction, followed sequentially by environmentally safe recycling, treatment, and disposal. In response to this act, DOE committed to voluntary participation in EPA's 33/50 Pollution Prevention Program, as set forth in Section 313 of SARA. The goal, for facilities already involved in Section 313 compliance, was to achieve a 33 percent reduction in release of 17 priority chemicals by 1997 from a 1993 baseline. LANL did not have releases that exceeded reportable thresholds for any of the 17 priority chemicals listed. In August 1993, Executive Order 12856 was issued, expanding the 33/50 program and requiring DOE to reduce its total release of all toxic chemicals by 50 percent by December 31, 1999. In response, DOE has developed Departmental Pollution Prevention Goals and Pollution Prevention Program Plans to meet these goals. Each DOE site, including LANL, develops its own site goals contributing to the DOE-wide goals and implements actions to achieve those goals. For Fiscal Year 1996, LANL met or exceeded all waste pollution prevention commitments.

7.7 COMMUNITY RIGHT-TO-KNOW AND EMERGENCY PLANNING

7.7.1 *Emergency Planning and Community Right-to-Know Act* and Executive Order 12856

This act is also known as SARA Title III. Section 313 of the EPCRA (42 U.S.C. §11001 *et seq.*) requires facilities meeting certain standard industrial classification code criteria to submit an annual toxic chemical release inventory report (*Toxic Chemical Release Reporting: Community-Right-to-Know* [40 CFR 372]). For facilities subject to the EPCRA requirements, a report describing the use of, and emissions from, Section 313 chemicals stored or used on site and meeting threshold planning quantities, must be submitted to EPA and the New Mexico Emergency Management Bureau every July for the preceding calendar year.

Other provisions of the EPCRA require planning notifications (Section 302–303), extremely hazardous substance release notifications (Section 304), and annual chemical inventory/Material Safety Data Sheet reporting (Section 311–312). Implementing regulations include but are not limited to *Emergency Planning and Notification* (40 CFR 355), *Material Safety Data Sheet Reporting* (40 CFR 370.21), and *Inventory Reporting* (40 CFR 370.28).

On August 3, 1993, Executive Order 12856, *Right-to-Know Laws and Pollution Prevention Requirements* directed all federal agencies to reduce and report toxic chemicals entering any waste stream; improve emergency planning, response, and accident notification; and encourage clean technologies and testing of innovative prevention technologies. Federal agencies were also defined as persons for the purposes of the EPCRA, requiring all federal facilities, regardless of standard industrial classification code to meet the requirements of the act.

LANL does not meet standard industrial classification code criteria for Section 313 reporting but has voluntarily submitted annual toxic chemical release inventory reports since 1987. All research operations are exempt under provisions of the regulation, and only pilot plants, production, or manufacturing operations at LANL are reported.

The *New Mexico Hazardous Chemicals Information Act* (74-4E-1 to 74-4E-9, NMSA 1978) implements the hazardous chemical information and toxic release reporting requirements of SARA Title III for covered facilities in New Mexico. Applicable reporting requirements under the provisions of the EPCRA and the state law are met by DOE and LANL in accordance with the executive order.

APPENDIX 7.A
CONSULTATIONS

In the process of preparing this SWEIS, DOE has had discussions with numerous organizations (including the New Mexico Department of Game and Fish, the BIA, the USFS, the NPS, and counties and municipalities near LANL) regarding issues, concerns, and interests associated with the operation of LANL and with the preparation of the SWEIS. Of these discussions, a few of them are considered to be consultations for the purposes of the SWEIS, where DOE specifically requested positions, advice, or input from organizations. The subjects of these consultations and the agencies or organizations consulted were:

SUBJECT OF CONSULTATIONS	AGENCIES OR ORGANIZATIONS CONSULTED
Threatened and Endangered Species	U.S. Fish and Wildlife Service
Environmental Monitoring Data	New Mexico Environment Department
Cultural Resources	New Mexico State Historic Preservation Office(r)
Traditional Cultural Properties[a]	Pueblo of Acoma Pueblo de Cochiti Pueblo of Jemez Pueblo of Laguna Pueblo of Nambe Jicarilla Apache Tribe Mescalero Apache Tribe Navajo Nation Hopi Tribe Pueblo of Picuris Pueblo of Pojoaque Pueblo of Sandia Pueblo of San Ildefonso Pueblo of Santa Clara Pueblo of Santa Domingo Pueblo of Taos Pueblo of Tesuque Pueblo of Zia Pueblo of Zuni Pueblo of San Juan Western Network New Mexico Acequia Association

[a] Many tribal governments and other organizations were contacted. Those listed here are the ones that agreed to a consultation relationship with DOE for the purposes of the SWEIS.

CHAPTER 8
LIST OF PREPARERS

Name:	**Mohammed Abu-Shehadeh**
Affiliation:	Parsons Brinckerhoff
Education:	Ph.D., Nuclear Engineering, University of Tennessee
Technical Experience:	6 years of experience in health physics
SWEIS Responsibility:	Radiological air quality impacts, radiological human health risk, radiological doses to workers, radioactive waste management impacts, radiological unusual occurrence reporting, and driver doses calculations for the transportation risk impacts

Name:	**Karen Agogino**
Affiliation:	U.S. Department of Energy
Education:	B.S., Civil Engineering, University of New Mexico
Technical Experience:	18 years of work experience, including 14 years in environmental and water resources
SWEIS Responsibility:	Lead Preparer for: water resources, geology and soils, environmental restoration, and project-specific analysis of the expansion of TA–54/Area G low-level waste disposal area

Name:	**Tom Anderson**
Affiliation:	Dames & Moore, Inc.
Education:	B.S., Botany, Ohio State University
Technical Experience:	24 years in preparation of NEPA documents for state and federal agencies
SWEIS Responsibility:	Technical Advisor (1996 to 1997)

Name:	**Randy Balice**
Affiliation:	Parsons Brinckerhoff
Education:	B.S., Biology, University of Utah M.S., Geography, University of Utah M.S., Statistics, University of Idaho Ph.D., Forestry, University of Idaho
Technical Experience:	24 years in biological and ecological sciences
SWEIS Responsibility:	Biological resources

Name:	**Dave Ball**
Affiliation:	GRAM, Inc.
Education:	B.S., Mechanical Engineering, University of New Mexico M.S., Civil/Environmental Engineering, New Mexico State University
Technical Experience:	25 years in engineering and management
SWEIS Responsibility:	Contractor (GRAM, Inc.) Project Manager (1995 to 1996)

Name:	**Michael J. Barr**
Affiliation:	Parsons Brinckerhoff
Education:	B.S., Ceramic Engineering, State University of New York at Alfred M.B.A., Business, University of New Mexico W.E.R.C., Certification, University of New Mexico
Technical Experience:	34 years of experience including: • 12 years in materials processing and development • 12 years in nuclear materials processing • 10 years in environmental engineering and waste management
SWEIS Responsibility:	Contaminated space estimation

Name:	**Rex Borders**
Affiliation:	U.S. Department of Energy
Education:	B.S., Health Physics, Elizabethtown College M.S., Nuclear Engineering, University of New Mexico
Technical Experience:	• 26 years of experience in health physics and nuclear engineering • Certified Health Physicist
SWEIS Responsibility:	Lead Preparer for radiological air quality; also participated in human health analysis

Name:	**Barry D. Boughton**
Affiliation:	Sandia National Laboratories
Education:	B.S., Mechanical Engineering M.S., Mechanical Engineering
Technical Experience:	1 year of experience in risk analysis
SWEIS Responsibility:	Transportation risk analysis

Name:	**Casey Brennan**
Affiliation:	Tetra Tech, Inc.
Education:	B.S., Civil Engineering, Brown University, Providence, Rhode Island
Technical Experience:	2 years of experience in NEPA analysis
SWEIS Responsibility:	Geology and soils and aircraft crash accident analyses

Name:	**Dana Nunez Brown**
Affiliation:	Parsons Brinckerhoff
Education:	M.L.A., Landscape Architecture, Harvard University B.L.A., Landscape Architecture, Louisiana State University, 1979
Technical Experience:	16 years of experience preparing environmental documents, visual assessments, landscape architecture, and geographic information systems
SWEIS Responsibility:	Land use

Name:	**Patricia Coffin**
Affiliation:	Systematic Management Services, Inc.
Education:	B.A., History, State University of New York at Binghamton
Technical Experience:	10 years of experience, including over 4 years in NEPA compliance
SWEIS Responsibility:	Comment Response Document (volume IV)

Name:	**Catherine Coghill**
Affiliation:	Parsons Brinckerhoff
Education:	B.A., Political Science & Sociology, St. Lawrence University M.S., Environmental Policy & Management, University of Denver
Technical Experience:	4 years of experience in public affairs associated with DOE NEPA projects
SWEIS Responsibility:	Community relations and cultural resources

Name:	**Ervin R. Copus**
Affiliation:	Sandia National Laboratories
Education:	B.S., Nuclear Engineering M.S., Nuclear Engineering
Technical Experience:	2 years of experience in risk assessment
SWEIS Responsibility:	Transportation risk analysis

Name:	**Corey Cruz**
Affiliation:	U.S. Department of Energy
Education:	B.S., Chemical Engineering, University of California, Berkeley M.S., Industrial Engineering, New Mexico State University
Technical Experience:	Over 13 years of experience in DOE program and project management
SWEIS Responsibility:	DOE Document Manager; also, Lead Preparer for: socioeconomics, infrastructure and waste management, environmental justice, transportation, and project-specific analysis of enhancement of plutonium pit manufacturing

Name:	**Rudolf Engelmann**
Affiliation:	Science Applications International Incorporated
Education:	B.A., Mathematics, Augsburg College Ph.D., Atmospheric Sciences, University of Washington
Technical Experience:	• 38 years of experience in environmental assessment and atmospheric sciences • Certified Consulting Meteorologist
SWEIS Responsibility:	Technical Advisor on human health, transportation, air quality, and accident analysis

Name:	**Ronald G. Faich**
Affiliation:	GRAM, Inc.
Education:	B.S., Math major, Physics minor, University of Wisconsin M.S., Sociology and Quantitative Research Methods, University of Wisconsin Ph.D., Sociology and Quantitative Research Methods, University of Wisconsin
Technical Experience:	35 years of experience in socioeconomic, demographic, cartographic and survey research
SWEIS Responsibility:	Socioeconomics and environmental justice

Name:	**Stephen Fong**
Affiliation:	U.S. Department of Energy
Education:	B.S., Mechanical Engineering, University of New Mexico
Technical Experience:	9 years of oversight of environmental compliance and monitoring programs at LANL, primarily in the area of ambient air quality
SWEIS Responsibility:	Air quality

Name:	**Nanette D. Founds**
Affiliation:	U.S. Department of Energy
Education:	Graduate Studies, Mechanical Engineering, University of New Mexico B.S., Aeronautical Engineering, Air Force Institute of Technology B.S., Chemistry, University of Nebraska, Lincoln
Technical Experience:	• Project Manager, Site-Wide Environmental Impact Statement for the Continued Operations of the Pantex Plant and Associated Storage of Nuclear Weapon Components • Project Manager, Operational Readiness Reviews, Albuquerque Operations Office • Branch Chief, Fluid Mechanics Branch, U.S. Air Force Weapons Laboratory
SWEIS Responsibility:	Lead Preparer for accident analysis

Name:	**F. David Freytag, AICP**
Affiliation:	Parsons Brinckerhoff
Education:	M.U.P., Urban and Regional Planning, College of Architecture, Texas A&M University B.E.D., Environmental Design, Texas A&M University
Technical Experience:	8 years of experience preparing environmental documents, transportation planning, and geographic information systems
SWEIS Responsibility:	Land use

Name:	**Joe Fritts**
Affiliation:	GRAM, Inc.
Education:	B.S., Geology, University of New Mexico
Technical Experience:	11 years of experience performing hydrogeologic site characterizations (includes work at environmental restoration and uranium tailings sites)
SWEIS Responsibility:	Geology and water resources

Name:	**Helen Ginzburg**
Affiliation:	Parsons Brinckerhoff
Education:	M.S., Air Quality, Leningrad Hydro Meteorological Institute
Technical Experience:	16 years in air quality meteorology and mathematical modeling
SWEIS Responsibility:	Nonradiological air quality

Name:	**Shiv N. Goel**
Affiliation:	U.S. Department of Energy
Education:	M.S., Environmental Engineering, University of New Mexico B.S., Mining Engineering, Indian School of Mines Registered Professional Engineer in the states of New Mexico and California
Technical Experience:	29 years of Environmental Engineering experience including: • 7 years as an Environmental Engineer responsible for DOE Albuquerque Operations Office • 2 years as a Supervisor of the Engineering Section for the City of Albuquerque Environmental Health Division • 4.5 years as a Supervisory Engineer/Environmental Engineer with the State of New Mexico, Environmental Improvement Division
SWEIS Responsibility:	Lead Preparer for nonradiological air analysis

Name:	**Timothy J. Goering**
Affiliation:	GRAM, Inc.
Education:	B.A., Environmental Science, University of Virginia M.S., Hydrology, University of Arizona
Technical Experience:	12 years of experience in environmental analysis and remediation
SWEIS Responsibility:	Environmental restoration

Name:	**Kathleen Gorman-Bates**
Affiliation:	GRAM, Inc.
Education:	B.S., Biology, St. Mary's College, Dodge City Kansas
Technical Experience:	9 years in radiochemistry, biology, microbiology, and health and safety
SWEIS Responsibility:	Nonradiological air quality

Name:	**Davin G. Greenly**
Affiliation:	Tetra Tech, Inc.
Education:	B.S., Environmental Engineering, California Polytechnic State University
Technical Experience:	2 years of experience in NEPA analysis
SWEIS Responsibility:	Aircraft crash accident analysis, transportation, and biological resources

Name:	**William L. Harrell**
Affiliation:	U.S. Department of Energy
Education:	B.S., Wildlife Science, Texas A&M University (with Honors) Graduate studies (20 hours), Environmental Science, Texas Christian University
Technical Experience:	27 years of experience in Environmental Protection and Compliance Programs, including planning and operations of federal water resource projects and DOE plants and laboratories; wildlife and ecological effects analysis and resource management; environmental restoration program and environmental compliance management; and NEPA compliance for federal projects
SWEIS Responsibility:	Lead Preparer for regulatory background and compliance (chapter 7)

Name:	**John Hogan**
Affiliation:	GRAM, Inc.
Education:	B.S., Biology, University of New Mexico
Technical Experience:	11 years of experience in field biology and ecology
SWEIS Responsibility:	Ecological risk and biodiversity

Name: **William R. James**
Affiliation: GRAM, Inc.
Education: B.S., Biological Sciences, Wright State University
M.S., Health Physics, University of Cincinnati
Technical Experience:
- 6 years in Occupational and Environment Health Physics
- 1 year in Emergency Preparedness
- 1 year in Occupational Health and Safety

SWEIS Responsibility: Radiological risk assessment for workers and on-site transportation

Name: **Kevin Keller**
Affiliation: Parsons Brinckerhoff
Education: B.A., Geography, California State University, Fullerton
Technical Experience: 8 years of experience preparing environmental documents, computer-aided drafting and design, and geographic information systems
SWEIS Responsibility: Land use

Name: **Jeffrey Kimball**
Affiliation: U.S. Department of Energy
Education: B.S., Oceanography, University of Michigan
M.S., Geology (Seismology), University of Michigan
Technical Experience: 17 years of experience, primarily in siting and design of critical facilities to resist the loads from natural phenomena
SWEIS Responsibility: Technical Advisor on geology (seismic) and accident analysis

Name: **J. Randall Kirchner**
Affiliation: H&R Technical Associates, Inc.
Education: B.S., Nuclear Engineering, University of Tennessee
Technical Experience: Over 13 years of experience in probabilistic risk assessment, nuclear facility safety analysis, and transportation risk analysis
SWEIS Responsibility: Transportation risk analysis

Name:	**Vadim Kogan**
Affiliation:	Parsons Brinckerhoff
Education:	Ph.D., Chemical Engineering, Moscow Institute of Chemical Technology
Technical Experience:	22 years in environmental engineering field
SWEIS Responsibility:	Nonradiological air quality

Name:	**John Lambright**
Affiliation:	BETA Corporation, International, and Self-Employed Consultant
Education:	B.S., Nuclear Engineering M.S., Nuclear Engineering Ph.D., Nuclear Engineering
Technical Experience:	More than 20 years in risk assessment, safety analysis, and hazards analysis
SWEIS Responsibility:	Accident analysis

Name:	**Alice Lovegrove**
Affiliation:	Parsons Brinckerhoff
Education:	B.E., State University of New York at Stony Brook M.S., State University of New York at Stony Brook
Technical Experience:	10 years in air quality
SWEIS Responsibility:	Nonradiological air quality

Name:	**Beth Medina**
Affiliation:	Parsons Brinckerhoff
Education:	B.A., Art, California State University, Long Beach
Technical Experience:	11 years of experience preparing environmental documents and graphics
SWEIS Responsibility:	Land use

Name:	**Paul E. McCluer**
Affiliation:	H&R Technical Associates, Inc.
Education:	B.S., Chemical Engineering, Tennessee Technological University
Technical Experience:	8 years of experience in DOE nuclear facility safety analysis and process hazards analysis in the refining and chemical processing industries and author or co-author of more than 30 reports and publications in the areas of DOE nuclear facility safety analysis and process hazards analysis
SWEIS Responsibility:	Transportation risk analysis

Name:	**Donna McCormick**
Affiliation:	Parsons Brinckerhoff
Education:	B.L.A., Landscape Architecture, California Polytechnic University
Technical Experience:	11 years of experience preparing environmental documents, visual assessments, and landscape architecture
SWEIS Responsibility:	Land use

Name:	**Jere Millard**
Affiliation:	Dames & Moore, Inc.
Education:	B.A., Biology & Psychology, Colorado State University M.S., Radiobiology, Colorado State University M.S., Health Physics, Colorado State University Ph.D., Health Physics, Colorado State University
Technical Experience:	18 years in radiation physics/radiation ecology
SWEIS Responsibility:	Human health and ecological risk

Name:	**Douglas Minnema**
Affiliation:	U.S. Department of Energy
Education:	B.S., Nuclear Engineering, University of Michigan M.S., Nuclear Engineering, University of Michigan M.S., Radiological Health, University of Michigan Ph.D. Candidate, Nuclear Engineering, University of New Mexico (in progress)
Technical Experience:	• 18 years in nuclear engineering, health physics, and radiological control • Certified Health Physicist
SWEIS Responsibility:	Lead Preparer for human health risk; Technical Advisor on transportation, and accident analysis

Name:	**Robert A. Monsalve-Jones**
Affiliation:	GRAM, Inc.
Education:	A.S., Nuclear Engineering, Pennsylvania State University B.S., Radiation Protection, Thomas Edison State College
Technical Experience:	24 years as a Radiation Protection Specialist and Health Physicist in nuclear powerplants and at decontamination and decommissioning projects, and performing environmental investigations, risk analysis, and dose assessments for DOE and private clients, nationally and internationally
SWEIS Responsibility:	Radioactive air quality and human health

Name:	**Elizabeth Mooney**
Affiliation:	Dames & Moore, Inc.
Education:	B.S., Zoology and Wildlife Ecology, Michigan State University M.A., Environmental Toxicology, The American University
Technical Experience:	• 10 years in toxicology • 5 years in risk assessment • 10 years in ecology
SWEIS Responsibility:	Ecological risk

Name:	**Abby Nagy**
Affiliation:	Dames & Moore, Inc.
Education:	B.S., Chemical Engineering, Ohio State University
Technical Experience:	7 years in chemical engineering process and environmental analysis
SWEIS Responsibility:	Transportation and environmental restoration

Name:	**Marilyn Norcini**
Affiliation:	GRAM, Inc.
Education:	M.A., History, Museum Studies, Cooperstown Graduate Programs, State University of New York, Oneonta M.A., Anthropology, University of Arizona Ph.D., Anthropology, University of Arizona
Technical Experience:	22 years of experience in cultural resources interpretation
SWEIS Responsibility:	Cultural resources

Name:	**Claudia Oakes**
Affiliation:	Parsons Brinckerhoff
Education:	Ph.D. (ABD), Geography, University of Texas at Austin
Technical Experience:	5 years as an environmental specialist in biogeographic studies and geophysical and cultural applications
SWEIS Responsibility:	Cultural resources

Name:	**John Ordaz**
Affiliation:	U.S. Department of Energy
Education:	B.S., Chemical Engineering, New Jersey Institute of Technology
Technical Experience:	20 years of experience, including over 7 years in DOE program management and NEPA compliance
SWEIS Responsibility:	DOE/HQ Program Manager; also, Lead Preparer for the Comment Response Document (volume IV)

Name:	**Carol S. Pazera**
Affiliation:	Parsons Brinckerhoff
Education:	B.A., Secondary Education, University of Illinois M.A., Latin American Studies, University of Texas at Austin M.S., Community and Regional Planning, University of Texas at Austin
Technical Experience:	3 years in socioeconomics
SWEIS Responsibility:	Socioeconomics

Name:	**Chuck Pergler**
Affiliation:	GRAM, Inc.
Education:	B.S., Range and Wildlands Science, University of California M.S., Range Management, University of California
Technical Experience:	14 years developing and implementing natural resource range plans, biological assessments, NEPA manager, and technical author
SWEIS Responsibility:	Biodiversity and ecological risk

Name:	**Susan Perlman**
Affiliation:	SWCA Environmental Consultants
Education:	B.S., Environmental Forestry, Colorado State University M.A., History, New Mexico State University
Technical Experience:	8 years of historical research in ethnography
SWEIS Responsibility:	Cultural resources

Name:	**Jeffrey P. Petraglia**
Affiliation:	Tetra Tech, Inc.
Education:	B.A., Nuclear Engineering, Pennsylvania State University
Technical Experience:	14 years of experience in safety and accident analyses
SWEIS Responsibility:	Aircraft crash accident analysis

Name:	**Beverly Ausmus Ramsey**
Affiliation:	Enterprise Advisory Services, Inc.
Education:	B.S., Chemistry/Biology M.S., Systems Ecology Ph.D., Systems Ecology
Technical Experience:	29 years of experience in environmental management and facility operations, especially radiological, hazardous and mixed waste management, facilities licensing, and regulatory compliance. Experience includes more than 25 years of experience in NEPA analysis and documentation, including human health impacts, ecological impacts, and cumulative impacts analysis
SWEIS Responsibility:	Technical Advisor on human health

Name:	**William R. Rhyne**
Affiliation:	H&R Technical Associates
Education:	B.S., Nuclear Engineering, University of Tennessee M.S., Nuclear Engineering, University of Virginia D.Sc., Nuclear Engineering, University of Virginia
Technical Experience:	• Over 30 years of experience in transportation risk analysis, DOE nuclear facility safety analysis, and commercial nuclear reactor safety analysis • Author or co-author of more than 50 reports and publications in the areas of transportation risk analysis and nuclear facility safety analysis • Author of Hazardous Materials Transportation Risk Analysis: Quantitative Approaches for Truck and Train
SWEIS Responsibility:	Transportation risk analysis

Name:	**Eric Rogoff**
Affiliation:	GRAM, Inc.
Education:	B.S., Geology, with Distinction, University of Kansas M.S., Hydrology, University of Arizona M.Phil., Geology, Yale University
Technical Experience:	7 years of experience in environmental consulting
SWEIS Responsibility:	Water resources, geology, and soils

Name:	**Francis Rowsome**
Affiliation:	U.S. Department of Energy
Education:	B.A., Physics (cum laude), Harvard University Graduate studies in theoretical physics, Cornell University
Technical Experience:	24 years of experience in nuclear safety engineering
SWEIS Responsibility:	Technical Advisor for accident analysis

Name:	**Noel Savignac**
Affiliation:	Self-employed Consultant
Education:	B.A., Biology, Lake Forest College M.S., Physiology, University of New Mexico Ph.D., Health Physics, Colorado State University
Technical Experience:	27 years in radiation protection, environmental assessment, and impact analyses
SWEIS Responsibility:	Human health

Name:	**Steve Sholly**
Affiliation:	BETA Corporation, International
Education:	B.S., Shippensburg State College
Technical Experience:	15 years in risk assessment, safety analysis, and hazards analysis
SWEIS Responsibility:	Accident analysis

Name:	**Mark Sifuentes**
Affiliation:	U.S. Department of Energy
Education:	B.S., Biology (Chemistry minor) M.S., Microbiology (Radiobiology minor)
Technical Experience:	28 years in NEPA compliance and biological sciences
SWEIS Responsibility:	Lead Preparer for: biological and ecological resources, and cultural resources

Name:	**Donald G. Silva**
Affiliation:	GRAM, Inc.
Education:	E.M.B.A., Management, University of New Mexico M.S.C.E., Air Pollution, New York University M.S., Industrial Hygiene, Environmental Health, Harvard University B.C.E., Sanitary Engineering, Manhattan College
Technical Experience:	• 38 years in environmental field including 27 years in direct NEPA documentation and methodology development • Diplomat of American Academy of Environmental Engineers
SWEIS Responsibility:	Contractor (GRAM, Inc.) Project Manager 1996 to 1997

Name:	**Bret E. Simpkins**
Affiliation:	Tetra Tech, Inc.
Education:	B.S., Nuclear Engineering, University of New Mexico M.S., Nuclear Engineering, University of New Mexico
Technical Experience:	13 years of experience in Safety and Accident Analyses
SWEIS Responsibility:	Accident analysis

Name:	**Constance L. Soden**
Affiliation:	U.S. Department of Energy
Education:	B.A., Radiation Biophysics
Technical Experience:	23 years of experience in the areas of occupational health and environmental protection
SWEIS Responsibility:	Lead Preparer for cumulative and unavoidable impacts

Name:	**Joel Soden**
Affiliation:	Parsons Brinckerhoff
Education:	M.S., Hunter College
Technical Experience:	• 24 years in air quality • Supervised a number of projects in various air quality fields
SWEIS Responsibility:	Nonradiological air quality

Name:	**John Stanford**
Affiliation:	GRAM, Inc.
Education:	B.A., Architecture, University of Houston M.S., City Planning, Georgia Tech
Technical Experience:	• 10 years in city/county urban planning • 3 years at Los Alamos National Laboratory, Facility Management
SWEIS Responsibility:	Land use

Name:	**Arlan Swihart**
Affiliation:	BETA Corporation, International
Education:	B.S., Emergency Administration and Planning, University of North Texas
Technical Experience:	• 3 years in solid waste management • 4.5 years in emergency planning/hazard management (hazard identification, scenario development, and consequence analysis)
SWEIS Responsibility:	Transportation analyses

Name:	**Erich C. Thomas**
Affiliation:	GRAM, Inc.
Education:	B.S., Western Washington University M.S., Western Washington University
Technical Experience:	17 years of technical geologic investigations and related assessments
SWEIS Responsibility:	Environmental restoration

Name:	**Gordon L. Tucker**
Affiliation:	GRAM, Inc.
Education:	M.S., Systems Management, University of Southern California M.S., Meteorology, University of Wisconsin B.S., Electrical Engineering, University of Massachusetts
Technical Experience:	• 25 years in meteorology/atmospheric science • 4 years of hazardous chemicals safety training
SWEIS Responsibility:	Air quality (meteorology and atmospheric dispersion modeling)

Name:	**Leonard R. Voellinger**
Affiliation:	Parsons Brinckerhoff
Education:	B.A., George Washington University M.A., Southwest Texas State University
Technical Experience:	19 years in cultural resource analysis and management
SWEIS Responsibility:	Cultural resources

Name:	**Darlene Williams**
Affiliation:	GRAM, Inc.
Education:	B.A., Geology and Mineralogy, Williams College
Technical Experience:	• 6 years in the hazardous waste management industry • Experience includes oversight work for the EPA, Remedial Investigation/Feasibility Study report preparation and work on DOE’s Transuranic Waste Program
SWEIS Responsibility:	Geology and soils

Name:	**Michael Williams**
Affiliation:	BETA Corporation, International
Education:	B.S., Environmental & Resource Management, Southwest Texas State University
Technical Experience:	10 years of experience in environmental assessments, environmental restoration, emergency response, accident analysis/ accident investigation, and regulatory compliance
SWEIS Responsibility:	Accident analysis and transportation analysis

Name:	**Elizabeth Withers**
Affiliation:	U.S. Department of Energy
Education:	B.S., Botany, Louisiana Tech University M.S., Life Sciences, Louisiana Tech University
Technical Experience:	16 years in environmental analysis experience, including 5 years in plant taxonomy and wetland ecology, 5 years in RCRA and CERCLA compliance and human health risk analysis, and 6 years in NEPA compliance
SWEIS Responsibility:	Lead Preparer for land resources; also participated in ecological resources analysis

Name:	**Steven Wolf**
Affiliation:	Parsons Brinckerhoff
Education:	M.S., Mathematics
Technical Experience:	22 years of preparing risk assessments to include noise and vibrations
SWEIS Responsibility:	Noise and vibration analysis

CHAPTER 9.0
LIST OF AGENCIES, ORGANIZATIONS, AND INDIVIDUALS TO WHOM COPIES OF THIS SWEIS HAVE BEEN SENT

UNITED STATES SENATE

The Honorable Jeff Bingaman
Washington, D.C.

The Honorable Jeff Bingaman
Albuquerque, New Mexico

The Honorable Jeff Bingaman
Subcommittee on Strategic Forces
Committee on Armed Services
Washington, D.C.

The Honorable Pete V. Domenici
Washington, D.C.

The Honorable Pete V. Domenici
Albuquerque, New Mexico

The Honorable Pete V. Domenici
Subcommittee on Energy and Water Development
Committee on Appropriations
Washington, D.C.

The Honorable Harry Reid
Subcommittee on Energy and Water Development
Committee on Appropriations
Washington, D.C.

The Honorable Robert Smith
Subcommittee on Strategic Forces
Committee on Armed Services
Washington, D.C.

UNITED STATES HOUSE OF REPRESENTATIVES

The Honorable Duncan Hunter
Subcommittee on Military Procurement
Committee on National Security
Washington, D.C.

The Honorable Ron Packard
Subcommittee on Energy and Water Development
Committee on Appropriations
Washington, D.C.

The Honorable Norman Sisisky
Subcommittee on Military Procurement
Committee on National Security
Washington, D.C.

The Honorable Joseph Skeen
Washington, D.C.

The Honorable Joseph Skeen
Roswell, New Mexico

The Honorable Thomas Udall
Washington, D.C.

The Honorable Thomas Udall
Santa Fe, New Mexico

The Honorable Peter Visclosky
Subcommittee on Energy and Water Development
Committee on Appropriations
Washington, D.C.

The Honorable Heather Wilson
Washington, D.C.

The Honorable Heather Wilson
Albuquerque, New Mexico

FOUR ACCORD PUEBLOS

Governor Isaac Herrera
Pueblo of Cochiti
Cochiti, New Mexico

Governor Raymond Gachupin
Pueblo of Jemez
Jemez, New Mexico

Governor Terry Aguilar
Pueblo de San Ildefonso
Santa Fe, New Mexico

Governor Walter Dasheno
Pueblo of Santa Clara
Española, New Mexico

PUEBLOS AND TRIBAL GOVERNMENTS

Northern Pueblos and Tribal Governments

Governor David Perez
Pueblo of Nambe
Santa Fe, New Mexico

Governor Eagle Rael
Pueblo of Picuris
Peñasco, New Mexico

Governor Jacob Viarrial
Pueblo of Pojoaque
Santa Fe, New Mexico

Governor Anthony Moquino
Pueblo of San Juan
San Juan, New Mexico

Governor Carl Concha
Pueblo of Taos
Taos, New Mexico

Governor Milton Herrera
Pueblo of Tesuque
Santa Fe, New Mexico

President Arnold Cassador
Jicarilla Apache Tribe
Dulce, New Mexico

President A. Paul Ortega
Mescalero Apache Tribe
Mescalero, New Mexico

President Kelsey Begay
Navajo Nation
Window Rock, Arizona

Southern Pueblos

Governor Lloyd Tortalita
Pueblo of Acoma
Acomita, New Mexico

Governor Alvino Lucero
Pueblo of Isleta
Isleta, New Mexico

Governor Harry Early
Pueblo of Laguna
Laguna, New Mexico

Governor Anthony Ortiz
Pueblo of San Felipe
San Felipe, New Mexico

Governor Inez Baca
Pueblo of Sandia
Bernalillo, New Mexico

Governor Bruce Sanchez
Pueblo of Santa Ana
Bernalillo, New Mexico

Governor Alex Bailon
Pueblo of Santo Domingo
Santo Domingo, New Mexico

Governor Amadeo Shije
Pueblo of Zia
Zia Pueblo, New Mexico

Governor Malcolm Bowekaty
Pueblo of Zuni
Zuni, New Mexico

ADDITIONAL TRIBAL AND PUEBLO GOVERNMENT AND ORGANIZATIONS

Stanley Pino, Chairman
All Indian Pueblo Council
Albuquerque, New Mexico

Bernie Teba, Director
Eight Northern Indian Pueblo Council
San Juan Pueblo, New Mexico

William Weahkee, Director
Five Sandoval Indian Pueblos, Inc.
Bernalillo, New Mexico

Leigh Jenkins
Hopi Cultural Preservation Office
Kykotsmovi, Arizona

Department of Environmental and Cultural Preservation
Pueblo de San Ildefonso
Santa Fe, New Mexico

FEDERAL AGENCIES

Don Klima
Advisory Council on Historic Preservation
Office of Planning and Review
Washington, D.C.

J. Michael Bremer
U.S. Department of Agriculture
Forest Service
Santa Fe National Forest
Santa Fe, New Mexico

Robert Remillard
U.S. Department of Agriculture
Santa Fe National Forest
Forest Service
Los Alamos, New Mexico

Mary Elizabeth Hoinkes
Arms Control and Disarmament Agency
Washington, D.C.

John Bellinger
U.S. Army Corps of Engineers
Office of Environmental Policy
Washington, D.C.

Carol McKinney
U.S. Army Corps of Engineers
Albuquerque, New Mexico

Bill Spurgeon
U.S. Army Corps of Engineers
Albuquerque, New Mexico

Assistant to the Secretary for
U.S. Department of Defense
Nuclear, Chemical, and Biological Defense Programs
Washington, D.C.

Albert G. Jordan
Defense Nuclear Facilities Safety Board
Washington, D.C.

Andrew Thibadeau
Defense Nuclear Facilities Safety Board
Washington, D.C.

Michael P. Jansky
U.S. Environmental Protection Agency
Dallas, Texas

Richard Sanderson
U.S. Environmental Protection Agency
Office of Federal Activities
Washington, D.C.

Bob Barker
U.S. Department of the Interior
Bureau of Indian Affairs
Albuquerque, New Mexico

Willie R. Taylor
U.S. Department of the Interior
Office of Environmental Policy and Compliance
Washington, D.C.

Jennifer Fowler-Propst
U.S. Department of the Interior
Fish and Wildlife Service
Albuquerque, New Mexico

Joel D. Lusk
U.S. Department of the Interior
Fish and Wildlife Service
Albuquerque, New Mexico

Stephen Fettig
U.S. Department of the Interior
National Park Service
Bandelier National Monument
Los Alamos, New Mexico

Brian Jacobs
U.S. Department of the Interior
National Park Service
Bandelier National Monument
Los Alamos, New Mexico

Roy Weaver
U.S. Department of the Interior
National Park Service
Bandelier National Monument
Los Alamos, New Mexico

William Cohen
U.S. Department of Justice
Washington, D.C.

Robert Fairweather
Office of Management and Budget
Washington, D.C.

Carl J. Paperiello
U.S. Nuclear Regulatory Commission
Office of Nuclear Material Safety and Safeguards
Washington, D.C.

NEW MEXICO STATE GOVERNMENT

Governor Gary Johnson
Santa Fe, New Mexico

Alletta Belin
Assistant Attorney General
Santa Fe, New Mexico

The Honorable Shannon Robinson
Albuquerque, New Mexico

Senator DeDe Feldman
Albuquerque, New Mexico

The Honorable Jeannette Wallace
State Representative
Los Alamos, New Mexico

Gedi Cibas
New Mexico Environment Department
Santa Fe, New Mexico

Michael Dale
New Mexico Environment Department/AIP
Los Alamos, New Mexico

Benito Garcia
New Mexico Environment Department
Santa Fe, New Mexico

Tom Tatkin
New Mexico Environment Department
Santa Fe, New Mexico

Mark Weidler
New Mexico Environment Department
Santa Fe, New Mexico

Regis Pecos
New Mexico Office of Indian Affairs
Santa Fe, New Mexico

Charles E. Spath
New Mexico State Land Office
Santa Fe, New Mexico

Steve Cary
Office of Natural Resources Trustee
Santa Fe, New Mexico

LANL SWEIS Cooperating Agency

Fred Brueggeman
Los Alamos County
Los Alamos, New Mexico

Denise Smith
Los Alamos County Council
Los Alamos, New Mexico

Lawry Mann
Los Alamos County Council
Los Alamos, New Mexico

Local Government

Mayor Ross Chavez
City of Española
Española, New Mexico

Mayor Larry Delgado
City of Santa Fe
Santa Fe, New Mexico

Companies and Institutions

Battelle
Evergreen, Colorado

Ann Berkley Rodgers
Chestnut Law Offices
Albuquerque, New Mexico

William Sayre
The College of Santa Fe
Santa Fe, New Mexico

Beth Ekerman
EASI
Oak Ridge, Tennessee

Betsy Kraus
EE&G
Albuquerque, New Mexico

Dave Peterson
Intera
Albuquerque, New Mexico

Bob Monslave-Jones
IT
Los Alamos, New Mexico

Cory Wilkinson
Lawrence Livermore National Laboratory
Germantown, Maryland

John Hickey
Los Alamos Economic Development Corp.
Los Alamos, New Mexico

Stephen Shankland
Los Alamos Monitor
Los Alamos, New Mexico

Tom Baca
Los Alamos National Laboratory
Los Alamos, New Mexico

Kathleen Gorman-Bates
Los Alamos National Laboratory
Los Alamos, New Mexico

Sue King
Los Alamos National Laboratory
Los Alamos, New Mexico

John Sisneros
Los Alamos National Laboratory
Los Alamos, New Mexico

Ron Stafford
Los Alamos National Laboratory
Los Alamos, New Mexico

Roger Mayes
Los Alamos Technical Associates, Inc.
Idaho Falls, Idaho

Paul Voilleque
MJP Risk Assessment, Inc.
Idaho Falls, Idaho

Institute for Policy Research
Northwestern University
Evanston, Illinois

Charles Thomas
Nuclear Tech. Consultants
Santa Fe, New Mexico

Our Lady of Guadalupe Parish
Taos, New Mexico

Suzan Dagg
Oxford Brookes University
Headington, Oxford
England

Bill Roman
Parsons Brinckerhoff
New York, New York

Joel Soden
Parsons Brinkerhoff
New York, New York

Larry Icerman
Regional Development Corp.
Santa Fe, New Mexico

Sue Martin/Abe Zeitoun
SAIC
Germantown, Maryland

Will Keener
Sandia National Laboratories
Albuquerque, New Mexico

Lucie Mayeux
Sandia National Laboratories
Albuquerque, New Mexico

Richard Orthen
Tetra Tech NUS, Inc.
Aiken, South Carolina

Steven Sholly
University of Vienna
Institute of Rusk Research
Vienna, Austria

Charlotte Lowrey
Women's Leadership Institute
Santa Fe, New Mexico

ORGANIZATIONS

Phil Bove
Acequia Madre
Santa Fe, New Mexico

Maureen Eldredge
Alliance for Nuclear Accountability
Washington, D.C.

Susan Gordon
Alliance for Nuclear Accountability
Seattle, Washington

Erlinda Gonzales
American Business Women's Association
Taos, New Mexico

Bryon Plumley
American Friends Service Committee
Denver, Colorado

Ernie Atencio
Amigos Bravos
Taos, New Mexico

Fred Griego III
Atrisco Land Rights Council
Albuquerque, New Mexico

Joani Berde
Carson Forest Watch
Llano, New Mexico

Rick Nielsen
Citizen Alert
Las Vegas, Nevada

Virginia Sanchez
Citizen Alert Native American Program
Reno, Nevada

Janet Greenwald
Citizens for Alternatives to Radioactive Dumping
Albuquerque, New Mexico

Douglas Doran
Citizens for Alternatives to Radioactive Dumping
Albuquerque, New Mexico

Carmi McLean
Clean Water Action
Denver, Colorado

Jay Coghlan
Concerned Citizens for Nuclear Safety
Santa Fe, New Mexico

David Bodde
U.S. Department of Energy
Environmental Management Advisory Board
Kansas City, Missouri

Douglas Costle
U.S. Department of Energy
Environmental Management Advisory Board
Woodstock, Vermont

Ann Dubois
U.S. Department of Energy
Northern New Mexico Citizens' Advisory Board
Los Alamos, New Mexico

Antonio Delgado
U.S. Department of Energy
Los Alamos National Laboratory Advisory Board
Ranchos de Taos, New Mexico

Tim Frazier
U.S. Department of Energy
Miamisburg, Ohio

Juan Griego
U.S. Department of Energy
Los Alamos, New Mexico

James Hoyal
U.S. Department of Energy
Albuquerque, New Mexico

Lucy Webster
Economists Allied for Arms Reduction
New York, New York

Fred Krupp
Environmental Defense Fund, Inc.
New York, New York

Tom Carpenter
Government Accountability Project
Seattle, Washington

Tom Clements
Greenpeace
Washington, D.C.

Arjun Makhijani
Institute for Energy and Environmental Research
Takoma Park, Maryland

Kevin O'Neill
Institute for Science and International Security
Washington, D.C.

Lorene Willis
Jicarilla Apache Culture Committee
Jicarilla Culture Center
Dulce, New Mexico

Alex Medina
Kiwanis Club
Taos, New Mexico

Sharon Lloyd-O'Connor
League of Women Voters
Washington, D.C.

Greg Mello
Los Alamos Study Group
Santa Fe, New Mexico

Jerilyn Christiansen
Mesa Public Library
Reference Department
Los Alamos, New Mexico

Robert Holden
National Congress of American Indians
Washington, D.C.

David J. Simon
National Parks and Conservation
Albuquerque, New Mexico

Jerry Pardilla
National Tribal Environmental Council
Albuquerque, New Mexico

David Beckman
Natural Resources Defense Council, Inc.
Los Angeles, California

Thomas V. Cochran
Natural Resources Defense Council, Inc.
Washington, D.C.

Doug Meiklejohn
New Mexico Environmental Law Center
Santa Fe, New Mexico

New Mexico Public Interest Group
Albuquerque, New Mexico

Steven Dolley
Nuclear Control Institute
Washington, D.C.

Mike Smith
Pajarito Group of the Sierra Club
Los Alamos, New Mexico

Bob Tiller
Physicians for Social Responsibility
Washington, D.C.

Maurice Weisberg
Physicians for Social Responsibility
Cedar Crest, New Mexico

David Culp
Plutonium Challenge
Washington, D.C.

T. R. Begay
Pueblo Environmental Protection
Albuquerque, New Mexico

Christine Chandler
Responsible Environmental Action League
Los Alamos, New Mexico

Melvin McCorkle
Responsible Environmental Action League
Los Alamos, New Mexico

Dale Oliffson
Rio Arriba Environmental Health Program
Center for Population Health
Albuquerque, New Mexico

LeRoy Moore, Ph.D.
Rocky Mountain Peace and Justice Center
Boulder, Colorado

Juan Montes
Rural Alliance for Military Accountability
Questa, New Mexico

Dolores Herrera
San Jose Community Awareness
Albuquerque, New Mexico

Mary Thaler
Sierra Club
Las Cruces, New Mexico

Richard Moore
Southwest Network for Environmental and Economic Justice
Albuquerque, New Mexico

Don Hancock
Southwest Research & Information Center
Albuquerque, New Mexico

Lynne Sebastian
State Historic Preservation Officer
Santa Fe, New Mexico

Kathy Albrecht
Taos Amistad
Taos, New Mexico

Corrine Sanchez
Tewa Women United
Española, New Mexico

Kathy Sanchez
Tewa Women United
Santa Fe, New Mexico

J. Gilbert Sanchez
Tribal Environmental Watch Alliance
Española, New Mexico

Deb Frey, Kelly Huddleston
The Trust for Public Lands
Santa Fe, New Mexico

Rosemary Romero
Western Network
Santa Fe, New Mexico

Bob McNeil
WIPP Environmental Evaluation Group
Albuquerque, New Mexico

INDIVIDUALS

Gary Andrews
Albuquerque, New Mexico

Arthur Apissomian
Wadena, Minnesota

Joni Arends
Santa Fe, New Mexico

Ray Armenta
Los Alamos, New Mexico

M. J. Barr
Jemez Springs, New Mexico

Kelly Black
Los Alamos, New Mexico

Bonnie Bonneau
El Prado, New Mexico

Richard Browning
Los Alamos, New Mexico

Shelley Buonaiuto
Santa Fe, New Mexico

Bruce & Loraine Buvinger
Albuquerque, New Mexico

Jessica Caplan
Madrid, New Mexico

Pat Casados
Los Alamos, New Mexico

Mary Ray Cate, M.D.
Santa Fe, New Mexico

Peter Chestnut
Albuquerque, New Mexico

Jody Clark
Socorro, New Mexico

Frank Clinard
Los Alamos, New Mexico

Barbara Conroy
Santa Fe, New Mexico

Al Cucchiara
Los Alamos, New Mexico

Shirley G. Davis
Santa Fe, New Mexico

Bob Day
Los Alamos, New Mexico

Robert Day
Los Alamos, New Mexico

Mike Dempseye
White Rock, New Mexico

Scott Denbaars
Los Alamos, New Mexico

Richard Deyo
Santa Fe, New Mexico

Elizabeth Dunham
Santa Fe, New Mexico

Gregg Eiesler
Los Alamos, New Mexico

John Eklund
Los Alamos, New Mexico

Eric Ericson
Santa Fe, New Mexico

Tom Farmer
Los Alamos, New Mexico

Eric Fern
Los Alamos, New Mexico

Geoff Fettos
Santa Fe, New Mexico

Thomas Francis
Santa Fe, New Mexico

L. Fredman
Albuquerque, New Mexico

J. K. Frenkel, M.D., Ph.D
Santa Fe, New Mexico

Clement Frost
Ingacio, California

Faith Garfield
Santa Fe, New Mexico

Richard L. Geddes
North Augusta, South Carolina

John Geddy
Albuquerque, New Mexico

Arlin Givens
Española, New Mexico

Don Diego Gonzales
Santa Fe, New Mexico

Chuck Grigsby
Los Alamos, New Mexico

Joe Guerrero
Albuquerque, New Mexico

Kay Hagan
Santa Fe, New Mexico

Mary G. P. Hallt
Santa Fe, New Mexico

Glen T. Hanson
Albuquerque, New Mexico

Ron Hardert
Tempe, Arizona

James Harrison
Los Alamos, New Mexico

M. Hassell
Albuquerque, New Mexico

Judy Herzl
Santa Fe, New Mexico

Marg-Anne Hesch
Santa Fe, New Mexico

Marcy Holloway
Austin, Texas

Judy Hutson
Los Alamos, New Mexico

Tracy Ikenberry
Richland, Washington

Fred A. Jenkins
Santa Fe, New Mexico

Terry Johnson
Los Alamos, New Mexico

Anna Katherine
Santa Fe, New Mexico

Nazir Khalil
Albuquerque, New Mexico

Janice M. King
Long Prairie, Minnesota

John King
Long Prairie, Minnesota

Timothy M. King
Long Prairie, Minnesota

Katherine Lage
Llano, New Mexico

R. W. Lang
Santa Fe, New Mexico

Melissa Larson
Rancho de Taos, New Mexico

Deirde Lennihan
Santa Fe, New Mexico

Betsy Lindsy

CHAPTER 10.0
GLOSSARY

This glossary lists terms of art or scientific expressions that may not be familiar to some readers of the SWEIS. The terms are defined as they are used in the SWEIS. Statutes or laws are defined and discussed in volume I of the SWEIS, chapter 7, Applicable Laws, Regulation, and Other Requirements.

Absorbed dose: The energy absorbed by matter from ionizing radiation per unit mass of irradiated material at the place of interest in that material. The absorbed dose is expressed in units of rad (or gray) (1 rad = 0.01 gray) (10 CFR 835.2).

Accident: Unexpected or undesirable event that leads to the release of hazardous material within a facility or into the environment, exposing workers or the public to hazardous materials or radiation.

Accord Pueblos: Four Pueblos that have each executed formal accord documents with DOE setting forth the government-to-government relationship between each of the Pueblos and DOE. The four Pueblos are Cochiti, San Ildefonso, Santa Clara, and Jemez.

Actinide: Any of a series of elements with atomic numbers ranging from actinium-89 through lawrencium-103.

Acute exposure: A single or short-term exposure to a toxic substance that may result in health effects.

Advisory Council of Historic Preservation (Council): An independent 19-member federal council created by the *National Historic Preservation Act of 1996*, Title II (16 U.S.C. §470 *et seq.*). The council meets quarterly to review and comment on National Register of Historic Places and Section 106 compliance cases.

Adverse effect: A change produced to an eligible cultural resource that results in demised integrity of location, setting, design, physical condition, materials, workmanship, feeling, or association. When applied to humans or animals, an undesirable health effect.

Air pollutant: Any substance in air that could, if in high enough concentration, harm humans, other animals, or vegetation.

Air quality standards: The level of pollutants in the air prescribed by regulations that may not be exceeded during a specified time in a defined area.

Alpha emitter: A radioactive substance that decays by releasing an alpha particle.

Alpha particle: A positively charged particle ejected spontaneously from the nuclei of some radioactive elements. It is identical to a helium nucleus and has a mass number of 4 and an electrostatic charge of +2. It has low penetrating power and a short range (a few centimeters in air).

Alpha radiation: A strongly ionizing, but weakly penetrating, form of radiation consisting of positively charged alpha particles emitted spontaneously from the nuclei of certain elements during radioactive decay. Alpha radiation is the least penetrating of the four common types of ionizing radiation (alpha, beta, gamma, and neutron). Even the most energetic alpha particle generally fails to penetrate the dead layers of cells covering the skin and can be easily stopped by a sheet of paper. Alpha radiation is most hazardous when an alpha-emitting source resides inside an organism.

Ambient air: That portion of the atmosphere, external to buildings, to which the general public is exposed.

Americium: Americium is a manmade metal that is slightly heavier than lead. Americium-241 is produced by the radioactive decay of plutonium-241; in addition to being an alpha-emitter, it is an emitter of gamma rays. Americium-241 has a half-life of 433 years.

Aquifer: Rock or sediment in a formation, group of formations, or part of a formation that is saturated and sufficiently permeable to conduct groundwater.

Archaeological sites (resources): Any location where humans have altered the terrain or discarded artifacts during either prehistoric or historic times.

Artifact: An object of archaeological or historical interest produced or shaped by human workmanship.

As low as reasonably achievable (ALARA): The approach to manage and control exposures (both individual and collective) to the workforce and to the general public to as low as is reasonable, taking into account social, technical, economic, practical, and public policy considerations. ALARA is not a dose limit but a process that has the objective of attaining doses as far below the applicable limits as is reasonably achievable (10 CFR 835.2).

Atomic Energy Commission (AEC): A five-member commission, established by the *Atomic Energy Act of 1946*, to supervise nuclear weapons design, development, manufacturing, maintenance, modification, and dismantlement. In 1974, the Atomic Energy Commission was abolished and all functions were transferred to the U.S. Nuclear Regulatory Commission and the Administrator of the Energy Research and Development Administration. The Energy Research and Development Administration was later terminated and its functions vested by law in the Administrator were transferred to the Secretary of Energy.

Atomic number: The number of positively charged protons in the nucleus of an atom or the number of electrons on an electrically neutral atom.

Attainment area: An area that the U.S. Environmental Protection Agency has designated as being in compliance with one or more of the National Ambient Air Quality Standards (NAAQS) for sulfur dioxide, nitrogen dioxide, carbon monoxide, ozone, lead, and particulate matter. An area may be in attainment for some pollutants but not for others.

Authorization/safety basis: Those aspects of the facility design basis and operational requirements relied upon by the DOE as necessary to authorize operation. These aspects are considered to be important to the safety of facility operations. The authorization basis is described in documents such as the facility Safety Analysis Report (SAR) and other safety analyses, hazard classification documents, the technical safety requirements (TSRs), DOE-issued safety evaluation reports, and facility-specific commitments made to comply with DOE orders or policies. Authorization basis is considered to be equivalent to safety basis. Authorization basis also is defined as a combination of authorization/safety basis, the environmental basis, and other regulatory basis documents.

Background radiation: Radiation from: (1) naturally occurring radioactive materials that have not been technologically enhanced, (2) cosmic sources, (3) global fallout as it exists in the environment (such as from the testing of nuclear explosive devices), (4) radon and its progeny in concentrations or levels existing in buildings or the environment that have not been elevated as a result of current or past human activities, and (5) consumer products containing nominal amounts of radioactive material or producing nominal levels of radiation (10 CFR 835.2).

Badged worker: A worker equipped with an individual dosimeter who has the potential to be exposed to radiation.

Baseline: A quantitative expression of conditions, costs, schedule, or technical progress to serve as a base or standard for measurement during the performance of an effort; the established plan against which the status of resources and the progress of a project can be measured. For the SWEIS, the environmental baseline is the site environmental conditions that are considered representative for the purpose of projecting future impacts.

Beryllium: An extremely lightweight, strong metal used in weapons systems.

Best available technology (BAT): Economically achievable pollution control methods that will allow point sources to comply with the effluent limitations required by the *Clean Water Act*. Factors to be taken into account in assessing what is the best available technology include the age of equipment and facilities involved, the process employed, the engineering aspects of the application of various types of control techniques, process changes, the cost of achieving such effluent reduction, environmental impacts other than water quality (including energy requirements), and such other factors as the U.S. Environmental Protection Agency Administrator deems appropriate.

Best management practices (BMPs): Structural, nonstructural, and managerial techniques, other than effluent limitations, to prevent or reduce pollution of surface water. They are the most effective and practical means to control pollutants that are compatible with the productive use of the resource to which they are applied. BMPs are used in both urban and agricultural areas. BMPs can include schedules of activities; prohibitions of practices; maintenance procedures; treatment requirements; operating procedures; and practices to control plant site runoff, spillage or leaks, sludge or waste disposal, or drainage from raw material storage.

Beta emitter: A radioactive substance that decays by releasing a beta particle.

Beta particle: A negatively charged particle emitted during the radioactive decay of many radionuclides. A beta particle is identical with an electron. It has a short range in air and a small ability to penetrate other materials.

Beta radiation: Ionizing radiation consisting of fast moving, positively or negatively charged elementary particles emitted from atomic nuclei during radioactive decay. Beta radiation is more penetrating but less ionizing than alpha radiation. Negatively charged beta particles are identical to electrons; positively charged beta particles are known as positrons. Both are stopped by clothing or a thin sheet of metal.

Biota: Living organisms including plants and animals.

Blast circle: The area wherein fragments from tests may fall and from which humans are excluded during tests.

Bound/bounding: To use simplifying assumptions and analytical methods in an analysis of impacts or risks such that the result overestimates or describes an upper limit on (i.e., "bounds") potential impacts or risks. A bounding analysis is an analysis designed to overestimate or determine an upper limit to potential impacts or risks. A bounding accident is a hypothetical accident for which the calculated consequences equal or exceed the consequences of all other potential accidents for a particular activity or facility.

Byproduct material: Any radioactive material (except special nuclear material) yielded in or made radioactive by exposure to the radiation incident to the process of producing or utilizing special nuclear material, and the tailings or wastes produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content. Byproduct material is exempt from regulation under the *Resource Conservation and Recovery Act*. However, the exemption applies only to the actual radionuclides dispersed or suspended in the waste substance. Any nonradioactive hazardous waste component of the waste is subject to regulation under the *Resource Conservation and Recovery Act*.

Caldera: A large crater formed by the collapse of the central part of a volcano.

Cancer: The name given to a group of diseases characterized by uncontrolled cellular growth with cells having invasive characteristics such that the disease can transfer from one organ to another.

Candidate species: Plants and animals native to the U.S. for which the U.S. Fish and Wildlife Service or the National Marine Fisheries Service has sufficient information on biological vulnerability and threats to justify proposing to add them to the threatened and endangered species list, but cannot do so immediately because other species have a higher priority for listing. The U.S. Fish and Wildlife Service and the National Marine Fisheries Service determine the relative listing priority of candidate taxa in accordance with general listing priority guidelines published in the *Federal Register*.

Canned subassemblies: A component in certain nuclear explosives that may contain natural, depleted, or highly enriched uranium or lithium. The "secondary" in a nuclear weapon.

Capability: The combination of equipment, facilities, infrastructure, and expertise required to undertake types or groups of activities and implement mission element assignments.

Cavate Pueblo: Structure making use of natural rock to form the sides of a single structure or group of buildings, frequently by hollowing out the interior space.

Cesium: A silver-white alkali metal. A radioactive isotope of cesium, cesium-137, is a common fission product.

Characteristic waste: A solid waste defined as hazardous because it exhibits one of the following four characteristics: ignitibility, corrosivity, reactivity, or toxicity.

Cladding: A metal coating bonded onto another metal.

Climatology: The characteristics of the weather over a period of time. The science of climatology addresses the causes, distribution, and effects of weather on the environment and humans.

Code of Federal Regulations (CFR): All federal regulations in force are published in codified form in the Code of Federal Regulations.

Cold War period: The historic period from 1949 to 1989, characterized by international tensions and nuclear armament buildup, especially between the U.S. and the U.S.S.R. The era began approximately at the end of World War II when the *Atomic Energy Act* was passed, establishing the Atomic Energy Commission, and ended with the dissolution of the U.S.S.R. into separate republics and the ending of large-scale nuclear weapons production in the U.S.

Collective dose: The sum of the total effective dose equivalent (TEDE) values of all individuals in a specified population. Collective dose is expressed in units of person-rem (or person-sievert) (10 CFR 835).

Committed dose equivalent (CDE): The dose equivalent calculated to be received by a tissue or organ over a 50-year period after the intake of radionuclide into the body. It does not include contributions from external dose. Committed dose equivalent is expressed in units of rem (or sievert) (10 CFR 835.2).

Committed effective dose equivalent (CEDE): The sum of the committed dose equivalents to various tissues of the body, each multiplied by the appropriate weighting factor. Committed effective dose equivalent is expressed in units of rem (or sievert) (10 CFR 835).

Community (biotic): All plants and animals occupying a specific area and their relationships.

Conceptual design: Efforts to develop a project scope that will satisfy program needs; ensure project feasibility and attainable performance levels of the project for congressional consideration; develop project criteria and design parameters for all engineering disciplines; and identify applicable codes and standards, quality assurance requirements, environmental studies, construction materials, space allowances, energy conservation features, health and safety, safeguards, security requirements, and any other features or requirements necessary to describe the project.

Contact-handled waste: Radioactive waste or waste packages with an external dose rate low enough to permit contact handling by humans during normal waste management activities. Contact-handled transuranic waste means transuranic waste with a surface dose rate not greater than 200 millirem per hour.

Container: The metal envelope in a waste package that provides the primary containment function of the waste package and is designed to meet the containment requirements of 10 CFR 60.

Contamination: The deposition or discharge of chemicals, radionuclides, or particulate matter above a given threshold, usually associated with an effects level onto or into environmental media, structures, areas, objects, personnel, or nonhuman organisms.

Cooperating agency: As defined by the Council on Environmental Quality regulations for implementing NEPA, any federal agency other than a lead agency that has jurisdiction by law of special expertise with respect to any environmental impact involved in a proposal (or a reasonable alternative) for legislation or other major federal action. A state or local agency of similar qualifications or, when the effects are on a reservation, an Indian tribe, may by agreement with the lead agency become a cooperating agency (40 CFR 1508.5).

Credible accident: An accident that has a probability of occurrence greater than or equal to once in a million years.

Criteria of effect: Regulations in 36 CFR Parts 800.5(a) and 800.9(b) and Section 106 of the *National Historic Preservation Act* (16 U.S.C. §470 *et seq.*) that provide guidelines for determining the kind and intensity of effect to an eligible cultural resource.

Criteria pollutant: Six air pollutants for which National Ambient Air Quality Standards are established by the U.S. Environmental Protection Agency: sulfur dioxide, nitric oxides, carbon monoxide, ozone, particulate matter-10 (smaller than 10 microns in diameter), and lead.

Critical habitat: Habitat essential to the conservation of an endangered or threatened species that has been designated as critical by the U.S. Fish and Wildlife Service or the National Marine Fisheries Service following the procedures outlined in the *Endangered Species Act* and its implementing regulations (50 CFR 424). The lists of critical habitats can be found in 50 CFR 17.95 (fish and wildlife), 50 CFR 17.96 (plants), and 50 CFR 226 (marine species).

Criticality event or accident: The accidental creation of an uncontrolled, self-sustaining nuclear chain reaction, accompanied by highly damaging external ionizing radiation.

Cultural resources: Any prehistoric or historic sites, buildings, structures, districts, or other places or objects (including biota of importance) considered to be important to a culture, subculture, or community for scientific, traditional, or religious purposes or for any other reason. In the SWEIS, prehistoric cultural resources refer to any material remains and items used or modified by people before the establishment of a European presence in the upper Rio Grande Valley in the early 17th Century; historic cultural resources include all material remains and any other physical alteration of the landscape that has occurred since the arrival of Europeans in the region.

Cultural resource site: The specific place or location of regular human occupation or use, as indicated by one or more forms of physical evidence.

Cultural resources survey: Evaluating the significance of the resources and their eligibility for inclusion in the National Register of Historic Places.

Cumulative impacts: The impact on the environment that results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or nonfederal), private industry, or individuals undertake such other actions. Cumulative impacts can result from individually minor, but collectively significant, actions taking place over a period of time (40 CFR 1508.7).

Curie (Ci): The conventional unit of activity in a sample of radioactive material. The curie is equal to 37 billion disintegrations per second, which is approximately the rate of decay of 1 gram of radium. A curie also is a quantity of any radionuclide that decays at a rate of 37 billion disintegrations per second.

Decay (radioactive): The decrease in the amount of any radioactive material with the passage of time, due to the spontaneous transformation of an unstable nuclide into a different nuclide or into a different energy state of the same nuclide; the emission of nuclear radiation (alpha, beta, or gamma radiation) is part of the process.

Decibel (dB): A unit of sound measurement. In general, a sound doubles in loudness for every increase of 10 decibels.

Decibel, A-weighted (dBa): A unit of weighted sound pressure level measured by the use of a metering characteristic and the “A” weighting specified by the American National Standards Institute (S1.4-1971[R176]).

Decommissioning: As used in this SWEIS, the process of decontamination, disassembly, and storage or disposal in a manner and state that assures future exposure of humans and the environment would be at acceptable levels.

Decontamination: The removal or reduction of radioactive or chemical contamination from facilities, equipment, or soils by washing, heating, chemical or electrochemical action, mechanical cleaning, or other techniques.

Depleted uranium (DU): Uranium containing less uranium-235 than the naturally occurring distribution of uranium isotopes.

Deposition: In geology, the laying down of potential rock-forming materials (sedimentation). In atmospheric sciences, the collection and retention of airborne particulates of gases on any solid or liquid surface (called dry deposition), or their removal from the air by precipitation (called wet deposition or precipitation scavenging).

Derived concentration guide (DCG): The concentration of a radionuclide in air or water that, under conditions of continuous exposure for 1 year by one exposure mode (e.g., ingestion of water, submersion in air, or inhalation of air), would result in an effective dose equivalent equal to the annual dose limit for that group exposed. For the public, this would be a dose of 100 millirem to a reference human who inhales 296,000 cubic feet (8,400 cubic meters) of air and ingests 195 gallons (730 liters) of water in a year.

Design basis accident: An accident postulated for the purpose of establishing functional and performance requirements for safety structures, systems, and components.

Design laboratory (or weapons laboratory): DOE facilities involved in the design of nuclear weapons.

Detailed operating procedure (DOP): Approved and authorized procedures for conducting a task.

Detriment: Negative effects from exposure to ionizing radiation. Harmful effects on health are called "health detriment."

Deuterium: A nonradioactive isotope of the element hydrogen with one neutron and one proton in the atomic nucleus.

Direct economic effects: The initial increases in output from different sectors of the economy resulting from some new activity within a predefined geographic region.

Direct effect multiplier: The total change in regional earnings and employment in all related industries as a result of one-dollar changes in earnings and an on-the-job change in a given industry.

Dismantlement: The process of taking apart a nuclear weapon or nuclear weapon component. This process takes place at LANL.

Dispersion: The downwind spreading of a plume by turbulence and meander in wind direction, resulting in a plume of lower concentration over a larger area.

Disposal: The process of placing waste in a final repository.

Disposal cell: Trench for disposal of low-level waste.

Disposition: The ultimate fate or end use of a surplus nuclear material or DOE facility following the transfer of the facility to the Office of the Assistant Secretary for Environmental Waste Management or the Director of the Office of Fissile Materials Disposition.

DOE orders: DOE directives that promulgate requirements and policies to DOE employees and contractors, including requirements to comply with other laws and regulations.

Dose (or radiation dose): The amount of energy deposited in body tissue as a result of radiation exposure. Various technical terms, such as absorbed dose, collective dose, dose equivalent, and effective dose equivalent, are used to evaluate the amount of radiation an exposed person receives. Each of these terms is defined in this glossary.

Dose equivalent: The product of absorbed dose in rad (or gray) in tissue, a quality factor, and other modifying factors. Dose equivalent is expressed in units of rem (or sievert) (1 rem = 0.01 sievert) (10 CFR 835.2).

Dosimeter: A device, instrument, or system that measures radiation dose (e.g., film badge or ionization chamber).

Drawdown: The height difference between the natural water level in a formation and the reduced water level in the formation caused by the withdrawal of groundwater.

Drinking-water standards: The prescribed level of constituents or characteristics in a drinking water supply that cannot be exceeded legally.

Ecology: A branch of science dealing with the interrelationships of living organisms with one another and with their nonliving environment.

Ecosystem: Living organisms and their nonliving (abiotic) environment functioning together as a community.

Ecotone: Transition zone between two adjacent distinct plant or animal communities.

Effective dose equivalent (EDE): The summation of the products of the dose equivalent received by specified tissues or organs of the body and the appropriate weighting factor. It includes the dose from radiation sources internal and/or external to the body. The effective dose equivalent is expressed in units of rem (or sievert) (10 CFR 835.2).

Effluent: A waste stream flowing into the atmosphere, surface water, groundwater, or soil. Most frequently the term applies to wastes discharged to surface waters.

Eligibility: The criteria of significance in American history, architecture, archeology, engineering, and culture. The criteria require integrity and association with lives or events, distinctiveness for any of a variety of reasons, or importance because of information the property does or could hold.

Eligible cultural resource: A cultural resource that has been evaluated and reviewed by an agency and the State Historic Preservation Office(r) and recommended as eligible for inclusion in the National Register of Historic Places, based on the criteria of significance.

Emission standards: Legally enforceable limits on the quantities and/or kinds of air contaminants that can be emitted into the atmosphere.

Endangered species: Plants and animals that are threatened with extinction, serious depletion, or destruction of critical habitat. Requirements for declaring a species endangered are contained in the *Endangered Species Act*.

Enduring stockpile: The U.S. nuclear stockpile of the future, consisting of fewer than 10 weapon systems (many of them older than their design lifetime), with no new systems added to the stockpile for the foreseeable future.

Energetic material: Generic term for high explosives and propellants.

Enriched uranium: A mixture of uranium isotopes that has greater amounts of the isotope uranium-235 than occur naturally. Naturally occurring uranium is nominally 0.720 percent uranium-235.

Environmental assessment (EA): A written environmental analysis that is prepared pursuant to the *National Environmental Policy Act* to determine whether a major federal action could significantly affect the environment and thus require preparation of an environmental impact statement. If the action would not significantly affect the environment, then a Finding of No Significant Impact is issued.

Environmental impact statement (EIS): A document required of federal agencies by the *National Environmental Policy Act* for proposals for legislation or major federal actions significantly affecting the quality of the human environment. A tool for decision making, it describes the positive and negative environmental impacts of the proposed action and alternative actions.

Environmental justice: A requirement of Executive Order 12898 for federal agencies to identify and address, as appropriate, disproportionately high and adverse human health or environmental impacts of federal programs, policies, and activities on minority and low-income populations.

Environmental monitoring: The process of sampling and analysis of environmental media in and around a facility being monitored for the purpose of: (1) confirming compliance with performance objectives and (2) early detection of any contamination entering the environment to facilitate timely remedial action.

Environmental Restoration (ER) Program: Program at LANL responsible for investigation and remediation of solid waste management units (SWMUs).

Ephemeral stream: A stream that flows only after a period of heavy precipitation.

Epicenter: The point on the Earth's surface directly above the focus of an earthquake.

Epidemiology: The science concerned with the study of events that determine and influence the frequency and distribution of disease, injury, and other health-related events and their causes in defined human populations.

Ethnographic: Information about cultural beliefs and practices.

Exposure limit: The legal limit of accumulated exposure (to ionizing radiation, nonionizing radiation, noise, chemicals, or other hazardous substances).

Exposure pathway: The course a chemical or physical agent takes from the source to the exposed organism. An exposure pathway describes a mechanism by which chemicals or physical agents at or originating from a release site reach an individual or population. Each exposure pathway includes a source or release from a source, an exposure route, and an exposure point. If the exposure point differs from the source, a transport/exposure medium such as air or water also is included.

Fabrication: For the purpose of the SWEIS, the terms "fabrication" and "manufacturing" are synonymous. See "manufacturing."

Fault: A fracture or a zone of fractures within a rock formation along which vertical, horizontal, or transverse slippage has occurred.

Finding of No Significant Impact (FONSI): A document by a federal agency briefly presenting the reasons why an action, not otherwise excluded, will not have a significant effect on the human environment and will not require an environmental impact statement.

Fissile material: Any material consisting of or containing one or more fissile radionuclides. Fissile radionuclides are plutonium-238, plutonium-239, plutonium-241, uranium-233, uranium-235, or any combination of these radionuclides. The definition does not apply to unirradiated natural uranium and depleted uranium, and natural uranium or depleted uranium that has been irradiated in a thermal reactor (49 CFR 173.403). DOE Order 5480.3 also includes curium-244 and neptunium-237 as fissile materials.

Fission: The splitting of a heavy atomic nucleus into two nuclei of lighter elements, accompanied by the release of energy and generally one or more neutrons. Fission can occur spontaneously or be induced by neutron bombardment.

Fission products: Nuclei formed by the fission of heavy elements (primary fission products); also, the nuclei formed by the decay of the primary fission products, many of which are radioactive.

Floodplains: The lowlands and relatively flat areas adjoining inland and coastal waters and the flood-prone areas of offshore islands. Floodplains include, at a minimum, that area with at least a 1.0 percent chance of being inundated by a flood in any given year.

The "base floodplain" is defined as the area that has a 1.0 percent or greater chance of being flooded in any given year. Such a flood is known as a 100-year flood.

The "critical action floodplain" is defined as the area that has at least a 0.2 percent chance of being flooded in any given year. Such a flood is known as a 500-year flood. Any activity for which even a slight chance of flooding would be too great (e.g., the storage of highly volatile, toxic, or water reactive materials) should not occur in the critical action floodplain.

Formation: In geology, the primary unit of formal stratigraphic mapping or description. Most formations possess certain distinctive features.

Fugitive emissions: Emissions to the atmosphere from pumps, valves, flanges, seals, and other process points not vented through a stack. Also includes emissions from area sources such as ponds, lagoons, landfills, and piles of stored material.

Fusion: The combining of two light nuclei (such as hydrogen isotopes or lithium) to form a heavier nucleus. Fusion is accompanied by the release of large amounts of energy.

Gamma radiation: High-energy, short wavelength, electromagnetic radiation emitted from the nucleus of an atom during radioactive decay. Gamma radiation frequently accompanies alpha and beta emissions and always accompanies fission. Gamma rays are very penetrating and are best stopped or shielded by dense materials, such as lead or depleted uranium. Gamma rays are similar to, but are usually more energetic than, x-rays.

Genetic effects: Changes in reproductive cells that may result in abnormal offspring of humans or animals (National Council on Radiation Protection [NCRP] 105).

Geology: The science that deals with the Earth: the materials, processes, environments, and history of the planet, including the rocks and their formation and structure.

Glovebox: An airtight box used to work with hazardous material, vented to a closed filtering system, having attached gloves that go into the box permitting work therein.

Groundwater: Water found beneath the Earth's surface.

Half-life (radiological): The time in which half the atoms of a radioactive substance undergo radioactive decay; this varies for specific radioisotopes from millionths of a second to billions of years.

Hazard analysis: The assessment of hazardous situations potentially associated with a process or activity. It includes the identification of material, system, process, and plant characteristics that can produce undesirable consequences. A safety analysis report hazard analysis examines the complete spectrum of potential accidents that could expose members of the public, on-site workers, facility workers, and the environment to hazardous materials. (See "Safety analysis report.")

Hazard category: Classification of nuclear facilities and operations for the potential of on-site and off-site effects from accidents. The criteria for distinguishing among hazard categories are found in DOE Order 5480.23, *Nuclear Safety Analysis Reports*.

Hazard index (HI): An indicator of the potential toxicological hazard from exposure to a particular substance; one such HI is the ratio of the estimated exposure to the estimated safe exposure. No toxicological effects would be expected where the HI is less than 1.0.

Hazardous air pollutants (HAPs): Air pollutants not covered by ambient air quality standards but that may present a threat of adverse human health effects or adverse environmental effects. Those specifically listed in 40 CFR 61.01 are asbestos, benzene, beryllium, coke oven emissions, inorganic arsenic, mercury, radionuclides, and vinyl chloride. More broadly, HAPs are any of the 189 pollutants listed in or pursuant to Section 112(b) of the *Clean Air Act*. Very generally, HAPs are any air pollutants that may realistically be expected to pose a threat to human health or welfare.

Hazardous material: A material, including a hazardous substance, as defined by 49 CFR 171.8 that poses a risk to health, safety, and property when transported or handled.

Hazardous waste: A solid waste that, because of its quantity, concentration, or physical chemical or infectious characteristics, may significantly contribute to an increase in mortality; or may pose a potential hazard to human health or the environment when improperly treated, stored, or disposed. The *Resource Conservation and Recovery Act of 1980* defines a "solid" waste as including solid, liquid, semisolid, or contained gaseous material (42 U.S.C. 6901 *et seq.*). By definition, hazardous waste has no radioactive components.

Heredity effects: Changes that are passed on to succeeding generation of offspring. See "Genetic effects."

High-efficiency particulate air (HEPA) filter: A throwaway, extended media, dry-type filter with a rigid casing enclosing the full depth of the pleats. The filter exhibits a minimum efficiency of 99.97 percent when tested with an aerosol of essentially monodispersed 0.3 micrometer diameter test aerosol particles.

High explosives (HE): Any chemical compound or mechanical mixture that, when subjected to heat, impact, friction, shock, or other suitable initiation stimulus, undergoes a very rapid chemical change with the evolution of large volumes of highly heated gases that exert pressure in the surrounding medium. Defined by 40 CFR 261.23 as any material that exhibits the characteristic of reactivity.

High explosives fabrication: The ability to fabricate any chemical compound or mechanical mixture that, when subjected to heat, impact, fraction, friction, shock, or other suitable initiation stimulus, undergoes a very rapid chemical change with the evolution of large volumes of highly heated gases that exert pressures in the surrounding medium.

High-level waste (HLW): The highly radioactive waste that results from reprocessing spent nuclear fuel and irradiated targets from reactors and is liquid before it is treated and solidified. LANL has no HLW in its inventory.

Highly enriched uranium (HEU): A mixture of uranium isotopes in which the abundance of the isotope uranium-235 is increased to 20 percent or more by weight, well above normal (naturally occurring) levels.

Historic context: A planning unit that is based on a shared theme, specific time period, and geographical area. Historical contexts are developed for predicting the types of sites and activities that may have taken place and determining how the sites might fit into the context. The evaluation process using the historic context to identify data deficits as criteria for evaluation.

Historic district: A significant concentration, linkage, or continuity of sites, buildings, structures, or objects historically or aesthetically united by plan or physical development and eligible for inclusion in the National Register of Historic Places because of cultural significance.

Hydrodynamic test: High-explosives nonnuclear experiment to investigate hydrodynamic aspects of primary function up to mid to late stages of pit implosion.

Hydrodynamics: The study of the motion of a fluid and of the interactions of the fluid with its boundaries, especially in the case of an incompressible inviscid fluid.

Hydrology: The science dealing with the properties, distribution, and circulation of water on and below the Earth's surface and in the atmosphere.

Implosion: Sudden inward compression and reduction in volume.

Incident-free risk: The risk of effects during normal conditions, not including the additional risk posed by incidents and accidents.

Index: A selected recent data set that is considered representative of current conditions and serves as a baseline for projecting future changes.

Indirect economic effects: Indirect effects result from the need to supply industries experiencing direct economic effects with additional outputs to allow them to increase their production. The additional output from each directly affected industry requires inputs from other industries within a region (i.e., purchases of goods and services). This results in a multiplier effect to show the change in total economic activity resulting from a new activity in a region.

Inertial confinement fusion (ICF): A laser-initiated nuclear fusion using the inertial properties of the reactants as a confinement mechanism.

Infrastructure: The basic services, facilities and equipment needed for the functioning and growth of an area.

Interim (permit) status: Period during which treatment, storage, and disposal facilities coming under the *Resource Conservation and Recovery Act of 1980* are temporarily permitted to operate while awaiting denial or issuance of a permanent permit.

Intersite: Transportation or other activities involving other sites.

Intrasite: Transportation or activities occurring solely within the boundaries of a facility.

Ion: An atom or molecule that has gained or lost one or more electrons to become electrically charged.

Ion exchange: A unit physiochemical process that removes ions, including radionuclides, from liquid streams (usually water) for the purpose of purification or decontamination.

Ionizing radiation: Radiation with sufficient energy to displace electrons from atoms or molecules, thereby producing ions.

Isolated find: A single artifact with no verifiable association with other cultural resources or other elements that would enlarge the historic information it contains.

Isotope: Nuclei of the same element with different numbers of neutrons are isotopes of the element. Isotopes have the same chemical properties but may have different radioactive properties.

Joint test assembly: A nonnuclear test configuration, with diagnostic instrumentation, of a warhead or bomb.

Key facility: Certain LANL facilities that were selected for special attention in the SWEIS. Selection criteria for key facilities are discussed in volume I, section 2.2.2 of the SWEIS.

Kiva: In this SWEIS, one of the remote-controlled critical assembly buildings associated with the Los Alamos Critical Experiment Facility (LACEF).

Laser: A device that produces a beam of monochromatic (single-color) "light" in which the waves of light are all in phase. This condition creates a beam that has relatively little scattering and has a high concentration of energy per unit area.

Latent cancer fatality (LCF): Death from cancer resulting from, and occurring some years after, exposure to excess ionizing radiation or other carcinogens.

Limiting condition for operation (LCO): The lowest functional capability or performance levels of safety-related structures, systems, components, and their support systems required for normal, safe operation of the facility.

Lithic scatter: Concentrations of stones showing evidence of human manufacturing of stone tools, including finished artifacts, roughly formed artifacts, the cores of stone from which they were made, and the waste flakes from the tool manufacturing process.

Low-income population: Community in which 25 percent or more of the population is characterized as living in poverty. The SWEIS uses the U.S. Bureau of the Census 1990 data to establish poverty thresholds; the 1990 poverty threshold for unrelated individuals was a 1989 income of $6,451 for those under age 65; $5,947 for those age 65 and older; and $12,674 for a family of four.

Low-level radioactive mixed waste (LLMW): Waste that contains both hazardous and low-level radioactive components. The hazardous component in LLMW is subject to regulation under the *Resource Conservation and Recovery Act of 1980*.

Low-level radioactive waste (LLW): All radioactive waste that is not classified as high-level waste, transuranic waste, spent nuclear fuel, or "11e(2) by-product material" as defined by DOE Order 5820.2A, *Radioactive Waste Management*. Byproduct material includes the tailings or waste produced by the extraction or concentration of uranium or thorium from any ore processed primarily for its source material content. Test specimens of fissionable material irradiated for research and development only, and not for the production of power or plutonium, may be classified as LLW, provided the concentration of transuranic waste is less than 100 nanocuries per gram.

Manufacturing: For the purpose of the SWEIS, the terms "fabrication" and "manufacturing" are synonymous. LANL has an existing capability to fabricate or manufacture plutonium parts. That is, the equipment, knowledge, supporting infrastructure, and administration procedures and controls exist at LANL to create plutonium metallic shapes to precise specifications. This capability is currently used in support of existing missions for research and development and to build prototypes of parts.

Maximally exposed individual (MEI): A hypothetical person whose location and habits result in the highest concentration or exposure and who takes no protective actions to lessen his or her exposure.

Maximum contaminant level (MCL): The MCL is the maximum permissible level of a contaminant in water that is delivered to any user of a public water system, as measured within the system or at entry points, depending upon the contaminant (40 CFR 141).

Megawatt (MW): A unit of power equal to 1 million watts. Megawatt thermal is commonly used to define heat produced, while megawatt electric defines electricity produced.

Meteorology: The science dealing with the atmosphere and its phenomena, especially as relating to weather.

Migration: The natural movement of a material through the air, soil, or groundwater; also, seasonal movement of animals from one area to another.

***Migratory Bird Treaty Act*:** This act states that it is unlawful to pursue, take, attempt to take, capture, possess, or kill any migratory bird, or any part, nest, or egg of any such bird other than permitted activities.

Minority population: Area where minority individuals comprise 25 percent or more of the population. Minority refers to people who classified themselves in the 1990 U.S. Census as African Americans, Asian or Pacific Islanders, American Indians, Hispanics of any race or origin, or other non-White races.

Mitigation: The alleviation of adverse impacts on resources by avoidance, by limiting the degree or magnitude of an action, by repair or restoration, by preservation and maintenance that reduces or eliminates the impact, or by replacing or providing substitute resources or environments.

Mixed oxide (MOX): A physical blend of uranium oxide and plutonium oxide that can be used as fuel in a nuclear reactor.

Mixed waste: See low-level radioactive mixed waste.

National Ambient Air Quality Standards (NAAQS): Air quality standards established by the *Clean Air Act*, as amended. The primary NAAQS are intended to protect the public health with an adequate margin of safety, and the secondary NAAQS are intended to protect the public welfare from any known or anticipated adverse effects of a pollutant.

National Emission Standards for Hazardous Air Pollutants (NESHAP): A set of national emission standards for listed hazardous pollutants emitted from specific classes or categories of new and existing sources. These standards were implemented in the *Clean Air Act Amendments of 1977*.

National Environmental Research Park (NERP): An outdoor laboratory set aside for ecological research to study the environmental impacts of energy developments. NERPs were established by DOE to provide protected land areas for research and education in the environmental sciences and to demonstrate the environmental compatibility of energy technology development and use.

National Pollutant Discharge Elimination System (NPDES): Federal permitting system required for hazardous effluents regulated through the *Clean Water Act*, as amended.

National Pollutant Discharge Elimination System Permit: Federal regulation (40 CFR Parts 122 and 125) requires permits for the discharge of pollutants from any point source into the waters of the U.S. regulated through the *Clean Water Act*, as amended.

National Register of Historic Places (NRHP): A list of districts, sites, buildings, structures, and objects of prehistoric or historic local, state, or national significance maintained by the Secretary of the Interior. The list is expanded as authorized by Section 2(b) of the *Historic Sites Act of 1935* (16 U.S.C. §462) and Section 101(a)(1)(A) of the *National Historic Preservation Act of 1966*, as amended.

Native American: A tribe, people, or culture that is indigenous to the U.S. Also referred to as American Indians.

Natural phenomena accidents: Accidents that are initiated by events such as earthquakes, tornadoes, floods, etc.

Neutron: An uncharged elementary particle with a mass slightly greater than that of the proton, found in the nucleus of every atom heavier than hydrogen-1. A free neutron is unstable and decays with a half-life of about 13 minutes into an electron and a proton.

Neutron flux: The product of neutron number density and velocity (energy) giving an apparent number of neutrons flowing through a unit area per unit time.

Noise: Unwanted or undesirable sound, usually characterized as being so loud as to interfere with, or be inappropriate to, normal activities such as communication, sleep, study, or recreation.

Noncriteria pollutant: A pollutant with an effects screening level guideline. Some noncriteria pollutants have a state standard as well.

Nonattainment area: An air quality control region (or portion thereof) in which the U.S. Environmental Protection Agency has determined that ambient air concentrations exceed National Ambient Air Quality Standards for one or more criteria pollutants.

Nondestructive evaluation: Test method that does not involve damage to or destruction of the test sample; this includes the use of ultrasonics, radiography, magnetic flux, and other techniques.

Nonnuclear component: Any one of the parts of a nuclear weapon that do not contain radioactive or fissile material.

Nonnuclear fabrication: Ability to fabricate nonnuclear components and perform nonnuclear component surveillance.

Nonproliferation: Preventing the spread of nuclear weapons, nuclear weapon materials, and nuclear weapon technology.

Nonproliferation Treaty: A treaty with the aim of controlling the spread of nuclear weapons technologies, limiting the number of nuclear weapons states, and pursuing, in good faith, effective measures relating to the cessation of the nuclear arms race. The treaty does not invoke stockpile reductions by nuclear states, and it does not address actions of nuclear states in maintaining their stockpiles.

Nuclear component: A part of a nuclear weapon that contains fissionable or fusionable material.

Nuclear facility: A facility with operations that involve radioactive materials in such form and quantity that a nuclear hazard potentially exists to the employees or the general public. Included are facilities that: produce, process, or store radioactive liquid or solid waste, fissionable materials, or tritium; conduct separations operations; or conduct irradiated materials inspection, fuel fabrication, decontamination, or recovery operations. Incidental use of radioactive materials in a facility operation (e.g., check sources, radioactive sources, and x-ray machines) does not necessarily require a facility to be included in this definition.

Nuclear warhead: A warhead that contains fissionable and fusionable material; the nuclear assembly and nonnuclear components packaged as a deliverable weapon.

Nuclear weapons complex: The set of interrelated federal sites and government-owned/contractor-operated facilities supporting the research, development, design, manufacture, testing, and maintenance of the nation's nuclear weapons and the subsequent dismantlement of retired weapons.

Off site (also off-site): As used in the SWEIS, the term denotes a location, facility, or activity occurring outside of the boundary of the entire LANL site.

On site (also on-site): As used in the SWEIS, the term denotes a location or activity occurring somewhere within the boundary of the LANL site.

Operable unit (OU): A discrete action that comprises an incremental step toward comprehensively addressing site problems. This discrete portion of a remedial response manages migration or eliminates or mitigates a release, threat of release, or pathway of exposure. The cleanup of a site can be divided into a number of operable units.

Outfall: The discharge point of a drain, sewer, or pipe as it empties into a body of water.

Packaging: The assembly of components necessary to ensure compliance with federal transportation regulations. It may consist of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shocks. The vehicle tie-down system and auxiliary equipment may be designated as part of the packaging.

Paleontology: A science dealing with life of past geological periods as known from fossil remains.

Paleontological resources: Fossils including those of microbial, plant, or animal origin.

Particulate matter (PM), PM_{10}, $PM_{2.5}$: Any finely divided solid or liquid material other than uncombined (i.e., pure) water. A subscript denotes the upper limit of the diameter of particles included. Thus, PM_{10} includes only those particles equal to or less than 10 micrometers (0.0004 inch) in diameter; $PM_{2.5}$ includes only those particles equal to or less than 2.5 micrometers (0.0001 inch) in diameter.

Perched aquifer: Groundwater separated from the underlying main body of groundwater, or aquifer, by unsaturated rock.

Perched groundwater: A body of groundwater of small lateral dimensions lying above a more extensive aquifer.

Performance assessment (PA): An analysis that predicts the behavior of a system or system component under a given set of conditions. In the context of "waste management activities," a systematic analysis of the potential risks posed by waste management systems to the public and environment, and a comparison of those risks to established performance objectives.

Permeability: The degree to which, or rate at which a fluid or gas can pass through a substance.

Perennial: Acting or lasting throughout the year or through many years (perpetual).

Person-rem: A redundancy meaning a dose of 1 rem. When used with a collective dose or population dose, it is a unit for expressing the dose when integrated across all people in the population.

Physical setting: The land and water form, vegetation, and structures that compose the landscape.

Pit: An assembly at the center of a nuclear device containing a subcritical mass of fissionable material.

Plume: The elongated pattern of contaminated air or water originating at a point source, such as a smokestack or a hazardous waste disposal site.

Plutonium: A heavy, radioactive, metallic element with the atomic number 94. It is produced artificially in a reactor by bombardment of uranium with neutrons and is used in the production of nuclear weapons.

Pollution prevention: Involves recycling or reduction of any hazardous substance, pollutant, or contaminate before generation, along with practices that protect natural resources through conservation or more efficient use.

Population dose: See "collective dose."

Potable: Suitable for drinking.

Pounds per square inch (psi): A measure of pressure. Atmospheric pressure is about 14.7 psi.

Prehistoric: Of, relating to, or existing in times antedating written history. In this SWEIS, prehistoric cultural resources refer to any material remains and items used or modified by people before the establishment of a European presence in the upper Rio Grande Valley in the early 17th Century.

Production: Fabrication or manufacturing of a relatively large quantity of items (as compared to the research and development and prototype capability). Production usually implies an effort to optimize material flows and improve efficiency and yield as well as the reliability of both the product and the process.

Programmatic environmental impact statement (PEIS): A broad-scope EIS prepared in accordance with the requirements of 102(2)(C) of NEPA that analyzes the environmental impacts of proposed federal policies or programs that involve multiple decisions potentially affecting the environment at one or more sites.

Project-specific environmental impact statement: An EIS prepared in accordance with the requirements of 102(2)(C) of NEPA that evaluates the environmental impacts of a single proposed action. See "Environmental impact statement."

Protected area: An area encompassed by physical barriers, subject to access controls, surrounding material access areas, and meeting the standards of DOE Order 5632.1C, *Protection and Control of Safeguards and Security Interests*.

Pueblo: The communal dwelling of an Indian village of Arizona, New Mexico, or adjacent areas consisting of contiguous flat-roofed stone or adobe houses in groups, sometimes several stories high; an Indian village of the southwestern U.S.; a member of a group of Indian peoples of the southwestern U.S.

Rad: See "Radiation absorbed dose."

Radiation: As used in the SWEIS, means ionizing radiation. The emitted particles or photons from the nuclei of radioactive atoms.

Radiation absorbed dose (rad): The basic unit of absorbed dose equal to the absorption of 0.01 joule per kilogram of absorbing material.

Radioactive: The state of emitting radiation energy in forms of waves (rays) or particles.

Radioactive waste: Materials from nuclear operations that are radioactive or are contaminated with radioactive materials, and for which use, reuse, or recovery are impractical.

Radioactivity: The spontaneous decay or disintegration of unstable atomic nuclei, accompanied by the emission of radiation.

Radioisotopes: See "Isotope."

Radionuclide: Any radioactive element.

Radon: A heavy gaseous, radioactive element with a half life of about 4 days from the decay of radium.

RADTRAN: A computer code combining user-determined meteorological, demographic, transportation, packaging, and material factors with health physics data to calculate the expected radiological consequences and accident risk of transporting radioactive material.

Raptor: Birds of prey including various types of hawks, falcons, eagles, vultures, and owls.

Recharge: Replenishment of water to an aquifer.

Record of Decision (ROD): A document prepared in accordance with the requirements of 40 CFR 1505.2 that provides a concise public record of DOE's decision on a proposed action for which an EIS was prepared. A ROD identifies the alternatives considered in reaching the decision, the environmentally preferable alternative(s), factors balanced by DOE in making the decision, whether all practicable means to avoid or minimize environmental harm have been adopted, and if not, why they were not.

Region of influence (ROI): Region in which the principal direct and indirect socioeconomic effects of actions are likely to occur and are expected to be of consequence for local jurisdictions.

Reliability: The ability of a nuclear weapon, weapon system, or weapon component to perform its required function under stated conditions for a specified period of time (essentially equivalent to performance).

Rem (roentgen equivalent man): The conventional unit or radiation dose equivalent. A unit of individual dose of absorbed ionizing radiation used to measure the effect on human tissue. The dosage of an ionizing radiation that will cause the same biological effect as one roentgen of x-ray or gamma-ray exposure.

Remediation: The decontamination of facilities or sites to an acceptable level of contamination suitable for general or specified use.

Remote-handled waste: In general, refers to radioactive waste that must be handled at a distance to protect workers from unnecessary exposure. "Remote-handled transuranic waste" means transuranic waste with a dose rate of 200 millirem per hour or more at the surface of the waste package.

Risk: A quantitative or qualitative expression of possible loss that considers both the probability that a hazard will cause harm and the consequences of that event.

Risk assessment (chemical or radiological): The qualitative and quantitative evaluation performed in an effort to define the risk posed to human health and/or the environment by the presence or potential presence and/or use of specific chemical or radiological materials.

Roentgen: A unit of exposure to ionizing x-ray or gamma radiation equal to 2.58×10^{-4} coulomb per kilogram. (A coulomb is a unit of electrical charge.) A roentgen is approximately equal to 1 rad.

Roentgen Equivalent Man (rem): See "Rem."

Runoff: The portion of rainfall, melted snow, or irrigation water that flows across the ground surface and may eventually enter streams.

Safety analysis report (SAR): A safety document providing a concise but complete description and safety evaluation of a site, design, normal and emergency operation, potential accidents, predicted consequences of such accidents, and the means proposed to prevent such accidents or mitigate their consequences. A safety analysis report is designated as final when it is based on final design information; otherwise, it is designated as preliminary.

Safe secure transport (SST): A specially designed trailer, used for transporting nuclear weapons or nuclear weapon components.

Safeguards and security: Program or actions with the express goal of elimination or minimizing the likelihood of unauthorized access to or loss of custody of a nuclear weapon or weapon system, nuclear materials, or sensitive or classified information.

Sanitary wastes: Liquid or solid (includes sludge) wastes that are not hazardous or radioactive and that are generated by industrial, commercial, mining, or agricultural operations or from community activities.

Scope: In a document prepared pursuant to the *National Environmental Policy Act of 1969*, the range of actions, alternatives, and impacts to be considered.

Scoping: Involves the solicitation of comments from interested people, groups, and agencies at public meetings, public workshops, in writing, electronically, or via fax to assist DOE in defining the proposed action, identifying alternatives, and developing preliminary issues to be addressed in an environmental impact statement.

Secondary (assembly): The component of a nuclear weapon that contains elements needed to initiate the fusion reaction in a thermonuclear reaction.

Section 106 process: A *National Historic Preservation Act* (16 U.S.C. §470 *et seq.*) review process used to identify, evaluate, and protect cultural resources eligible for nomination to the National Register of Historic Places that may be affected by federal actions or undertakings.

Sedimentation: The settling out of soil and mineral solids from suspensions under the force of gravity.

Seismic: Pertaining to any earth vibration, especially an earthquake.

Seismic zone: Geographic region that is assumed to possess uniform earthquake potential throughout.

Seismicity: Occurrence of earthquakes in space and time.

Setting: The physical environment of a property.

Severe accident: An accident with a frequency rate of less then 10^{-6} per year that would have more severe consequences than a design-basis accident, in terms of damage to the facility, off-site consequences, or both.

Sewage: The total of organic waste and wastewater generated by an industrial establishment or a community.

Shielding: A material placed between a radiation source and a receptor that absorbs the radiation, thus reducing the exposure to the receptor.

Short-lived nuclides: Radioactive isotopes with half-lives no greater than about 30 years (e.g., cesium-137 and strontium-90).

Site-wide environmental impact statement (SWEIS): A type of programmatic EIS that analyzes the environmental impacts of all or selected functions at a DOE site. As part of its regulations for implementation of NEPA, DOE prepares site-wide EISs for certain large, multiple-facility DOE sites; it may prepare EISs or EAs for other sites to assess the impacts of all or selected functions at those sites (10 CFR 1021.330 [c]).

Socioeconomics: The social and economic condition in the study area.

Solid waste management unit (SWMU): Any unit from which hazardous constituents may migrate, as defined by the *Resource Conservation and Recovery Act.* A designated area that is or is suspected to be the source of a release of hazardous material into the environment that will require investigation and/or corrective action.

Source material: In general, material from which special nuclear material can be derived. Under the *Atomic Energy Act* and U.S. Nuclear Regulatory Commission regulations, "source material" means uranium and thorium in any physical or chemical form, as well as ores that contain 1/20 of 1 percent (0.05 percent) or more by weight of uranium or thorium.

Source term: The quantity of material released and parameters such as exhaust temperature that determine the downwind concentration, given a specific meteorological dispersion condition.

Special nuclear material (SNM): As defined in Section 11 of the *Atomic Energy Act of 1954*, special nuclear material means (1) plutonium, uranium enriched in the isotope 233 or in the isotope 235, and any other material that the U.S. Nuclear Regulatory Commission determines to be special nuclear material or (2) any material artificially enriched by any of the foregoing.

Species of concern: Includes species that are considered to be potential candidates for addition to the List of Endangered Species (50 CFR 17) by the federal agency responsible for *Endangered Species Act* compliance oversight, the U.S. Fish and Wildlife Service. These are primarily species for which there is insufficient information on biological vulnerability and threat to warrant legal protection.

Stabilization: Actions taken to further confine or reduce the hazards associated with residues as necessary for safe management and responsible storage.

START I and II: Strategic Arms Reduction Talks (also Treaty) (START) refer to negotiations between the U.S. and the U.S.S.R. (the former Soviet Union during START I negotiations) aimed at limiting and reducing nuclear arms. START I discussions began in 1982 and eventually led to a ratified treaty in 1988. START II discussions, which are now in progress, will attempt to further reduce the acceptable levels of nuclear weapons ratified in START I.

State Historic Preservation Office(r) (SHPO): A position in each U.S. state that coordinates state participation in the implementation of the *National Historic Preservation Act* (16 U.S.C. §470 *et seq.*). The SHPO is a key participant in the Section 106 process, assisting in the steps of identification of eligible resources, evaluating effects of undertakings, and developing mitigation measures or management plans to reduce any adverse effects to eligible cultural resources.

Stockpile management: Operations associated with producing, maintaining, refurbishing, surveilling, and dismantling the nuclear weapons stockpile.

Stockpile stewardship: Activities associated with research, design, development, and testing of nuclear weapons and the assessment and certification of their safety and reliability.

Stockpile surveillance: Routine and periodic examination, evaluation, and testing of stockpile weapons and weapon components to ensure that they conform to performance specifications and to identify and evaluate the effect of unexpected or age-related requirements.

Strike: The direction or trend that a structural surface (e.g., a bedding or fault plane) takes as it intersects the horizontal.

Surface water: Water on the Earth's surface, as distinguished from water in the ground (groundwater).

Technical safety requirements (TSRs): Those requirements that define the conditions, the safe boundaries, and the management or administrative controls necessary to ensure the safe operation of a nuclear facility and to reduce the potential risk to the public and facility workers from uncontrolled releases of radioactive materials or from radiation exposures due to inadvertent criticality. TSRs consist of safety limits, operating limits, surveillance requirements, administrative controls, use and application instructions, and the basis thereof. TSRs were formerly known as "operational safety requirements" for nonreactor nuclear facilities and "technical specifications" for reactor facilities.

Threatened and endangered (T&E) species: Animals, birds, fish, plants, or other living organisms threatened with extinction by human-produced or natural changes in their environment. Requirements for declaring species threatened or endangered are contained in the *Endangered Species Act of 1973*.

Total effective dose equivalent (TEDE): The sum of the effective dose equivalent from external exposures and the committed effective dose equivalent from internal exposures (10 CFR 835).

Toxic waste: Individual chemical wastes (liquid or solid), such as polychlorinated biphenyls or asbestos, that are regulated by the *Toxic Substances Control Act*.

Transuranic (TRU) waste: Waste, without regard to source or form, that is contaminated with alpha-emitting radionuclides of atomic number greater than 92 (uranium) and with half-lives greater than 20 years in concentrations greater than 100 nanocuries per gram.

Traditional cultural property (TCP): A significant place or object associated with historical and cultural practices or beliefs of a living community that is rooted in that community's history and is important in maintaining the continuing cultural identity of the community.

Tritium: A radioactive isotope of the element hydrogen with two neutrons and one proton. Common symbols for the isotope are H–3 and T.

Unreviewed safety question: A proposed change, test, or experiment is considered to involve an unreviewed safety question if: (1) the probability of occurrence or the consequences of an accident or malfunction of equipment important to safety evaluated previously by safety analyses will be significantly increased or (2) a possibility for an accident or malfunction of a different type than any evaluated previously by safety analyses will be created that will result in significant safety consequences.

Uranium: A heavy, silvery-white metallic element (atomic number 92) with many radioactive isotopes. Uranium-235 is most commonly used as a fuel for nuclear fission. Another isotope, uranium-238, can be transformed into fissionable plutonium-239 by its capture of a neutron in a nuclear reactor.

Volatile organic compounds (VOCs): A broad range of organic compounds, often halogenated, that vaporize at ambient or relatively low temperatures, such as benzene, chloroform, and methyl alcohol.

War reserve: Operational weapons and materials designated as essential for national security needs.

Waste acceptance criteria (WAC): Requirements established by treatment, storage, and disposal facilities for the acceptance of waste into a facility.

Waste characterization: The identification of waste composition and properties by reviewing process knowledge, nondestructive examination, nondestructive assay, or sampling and analysis. Characterization provides the basis for determining appropriate storage, treatment, handling, transportation, and disposal requirements.

Waste generator: For the purpose of the SWEIS, any individual or group of individuals who generate radioactive, mixed, hazardous, or other types of wastes at LANL.

Waste Isolation Pilot Plant (WIPP): A DOE facility designed and authorized to permanently dispose of transuranic radioactive waste in a mined underground facility in deep geologic salt beds. It is located in southeastern New Mexico, 26 miles (42 kilometers) east of the City of Carlsbad.

Waste management: The planning, coordination, and direction of those functions related to generation, handling, treatment, storage, transportation, and disposal of waste, as well as associated pollution prevention, surveillance, and maintenance activities.

Waste minimization: Actions that economically avoid or reduce the generation of waste by source reduction, by reducing the toxicity of hazardous waste, by improving energy usage, or by recycling.

Watershed: For the purposes of the SWEIS, a watershed was defined as that region contributing water to major identified stream channels, which ultimately become tributaries or drain into tributaries to an 11-mile (18-kilometer) segment of the Rio Grande between Otowi Bridge and Frijoles Canyon.

Weapon component: An item in a nuclear weapon that can be either an assembly or individual subset of an assembly. The word “component” can be used interchangeably with “part” or “subassembly.”

Weapons laboratories: Colloquial term for the three DOE national laboratories—Los Alamos, Lawrence Livermore, and Sandia—that are responsible for the design, development, and stewardship of U.S. nuclear weapons.

Weapon system: Collective term for the nuclear assembly and nonnuclear components, subsystems, and systems that compose a nuclear weapon.

Wetland: Land or areas exhibiting hydric (requiring considerable moisture) soil concentrations, saturated or inundated soil during some portion of the year, and plant species tolerant of such conditions.

Whole-body dose: Dose resulting from the uniform exposure of all organs and tissues in a human body.

Wind rose: A depiction of wind speed and direction frequency for a given period of time.

X-rays: Penetrating electromagnetic radiation having a wavelength much shorter than that of visible light. X-rays are identical to gamma rays, but originate outside the nucleus, either when the inner orbital electrons of an excited atom return to their normal state or when a metal target is bombarded with high-speed electrons.

CHAPTER 11.0
CONTRACTOR DISCLOSURE STATEMENTS

DE-AC04-94AL85382

QUALIFICATION CRITERION NO. 1

NEPA DISCLOSURE STATEMENT FOR PREPARATION OF THE LANL SWEIS FOR DOE NUCLEAR WEAPONS COMPLEX MODERNIZATION

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term "financial interest or other interest in the outcome of the project" for purposes of this disclosure is defined in the March 23, 1981, guidance "Forty Most Asked *Questions Concerning CEQ's National Environmental Policy Act Regulations*", 46 FR 18026-18038 at Question 17a and b.

"Financial or other interest in the outcome of the project" includes "any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm's other clients)". See 46 FR 18026-18031.

In accordance with these requirements, the offeror and any proposed subcontractors hereby certify as follows: (check either (a) or (b) and list financial or other interest if (b) is checked).

(a) ☒ Contractor has no financial or other interest in the outcome of the project.

(b) ☐ Offeror and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

NEPA DISCLOSURE STATEMENT FOR
PREPARATION OF THE LANL SWEIS FOR DOE NUCLEAR
WEAPONS COMPLEX MODERNIZATION

CEQ Regulations at 40 CFR 1506.5(c), which have been adopted by the DOE (10 CFR 1021), require contractors who will prepare an EIS to execute a disclosure specifying that they have no financial or other interest in the outcome of the project. The term "financial interest or other interest in the outcome of the project" for purposes of this disclosure is defined in the March 23, 1981, guidance "Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations", 46 FR 18026-18038 at Question 17a and b.

"Financial or other interest in the outcome of the project" includes "any financial benefit such as a promise of future construction or design work in the project, as well as indirect benefits the contractor is aware of (e.g., if the project would aid proposals sponsored by the firm's other clients)". See 46 FR 18026-18031.

In accordance with these requirements, the offeror and any proposed subcontractors hereby certify as follows" (check either (a) or (b) and list financial or other interest if (b) is checked).

(a) ☒ Contractor has no financial or other interest in the outcome of the project.

(b) ☐ Offeror and any proposed subcontractor have the following financial or other interest in the outcome of the project and hereby agree to divest themselves of such interest prior to award of this contract.

THE LOS ALAMOS NATIONAL LABORATORY SITE-WIDE ENVIRONMENTAL IMPACT STATEMENT PROCESS

The United States Department of Energy (DOE) has a policy (10 Code of Federal Regulations [CFR] 1021.330) of preparing a Site-Wide Environmental Impact Statement (SWEIS) for certain large, multiple-facility sites, such as the Los Alamos National Laboratory (LANL). The purpose of a SWEIS is to provide DOE and its stakeholders with an analysis of the environmental impacts resulting from ongoing and reasonably foreseeable new operations and facilities and reasonable alternatives at the DOE site. The SWEIS analyzes four alternatives for the continued operation of LANL to identify the potential effects that each alternative could have on the human environment.

The SWEIS Advance Notice of Intent, published in the *Federal Register* (FR) on August 10, 1994 (59 FR 40889), identified possible issues and alternatives to be analyzed. Based on public input received during prescoping, DOE published the Notice of Intent to prepare the SWEIS in the *Federal Register* on May 12, 1995 (60 FR 25697). DOE held a series of public meetings during prescoping and scoping to provide opportunities for stakeholders to identify the issues, environmental concerns, and alternatives that should be analyzed in the SWEIS. An Implementation Plan[1] was published in November 1995 to summarize the results of scoping, describe the scope of the SWEIS based on the scoping process, and present an outline for the draft SWEIS. The Implementation Plan also included a discussion of the issues reflected in public comments during scoping.

In addition to the required meetings and documents described above, the SWEIS process has included a number of other activities intended to enhance public participation in this effort. These activities have included:

- Workshops to develop the Greener Alternative described and analyzed in the SWEIS.
- Meetings with and briefings to representatives of federal, state, tribal, and local governments during prescoping, scoping, and preparation of the draft SWEIS.
- Preparation and submission to the Los Alamos Community Outreach Center of information requested by members of the public related to LANL operations and proposed projects.
- Numerous Open Forum public meetings in the communities around LANL to discuss LANL activities, the status of the SWEIS, and other issues raised by the public.

The draft SWEIS was distributed to interested stakeholders for comment. The comment period extended from May 15, 1998, to July 15, 1998. Public hearings on the draft SWEIS were announced in the *Federal Register*, as well as community newspapers and radio broadcasts. Public hearings were held in Los Alamos, Santa Fe, and Española, New Mexico, on June 9, 1998, June 10, 1998, and June 24, 1998, respectively.

Oral and written comments were accepted during the 60-day comment period for the draft SWEIS. All comments received, whether orally or in writing, were considered in preparation of the final SWEIS. The final SWEIS includes a new volume IV with responses to individual comments and a discussion of general major issues. DOE will prepare a Record of Decision no sooner than 30 days after the final SWEIS Notice of Availability is published in the *Federal Register*. The Record of Decision will describe the rationale used for DOE's selection of an alternative or portions of the alternatives. Following the issuance of the Record of Decision, a Mitigation Action Plan may also be issued to describe any mitigation measures that DOE commits to in concert with its decision.

---

1. DOE *National Environmental Policy Act* regulations (10 CFR 1021) previously required that an implementation plan be prepared; a regulation change (61 FR 64604) deleted this requirement. An implementation plan was prepared for this SWEIS.

COVER SHEET

Responsible Agency: U.S. Department of Energy (DOE)

Cooperating Agency: Incorporated County of Los Alamos

Title: Site-Wide Environmental Impact Statement for the Continued Operation of the Los Alamos National Laboratory, Los Alamos, New Mexico (DOE/EIS-0238)

Telephone: 202–586–4600 or leave a message at 1–800–472–2756

Abstract: DOE proposes to continue operating the Los Alamos National Laboratory (LANL) located in Los Alamos County, in north-central New Mexico. DOE has identified and assessed four alternatives for the operation of LANL: (1) No Action, (2) Expanded Operations, (3) Reduced Operations, and (4) Greener. Expanded Operations is DOE's Preferred Alternative, with the exception that DOE would only implement pit manufacturing at a level of 20 pits per year. In the No Action Alternative, DOE would continue the historical mission support activities LANL has conducted at planned operational levels. In the Expanded Operations Alternative, DOE would operate LANL at the highest levels of activity currently foreseeable, including full implementation of the mission assignments from recent programmatic documents. Under the Reduced Operations Alternative, DOE would operate LANL at the minimum levels of activity necessary to maintain the capabilities to support the DOE mission in the near term. Under the Greener Alternative, DOE would operate LANL to maximize operations in support of nonproliferation, basic science, materials science, and other nonweapons areas, while minimizing weapons activities. Under all of the alternatives, the affected environment is primarily within 50 miles (80 kilometers) of LANL. Analyses indicate little difference in the environmental impacts among alternatives. The primary discriminators are: collective worker risk due to radiation exposure, socioeconomic effects due to LANL employment changes, and electrical power demand.

Public Comment and DOE Decision: The draft SWEIS was released to the public for review and comment on May 15, 1998. The comment period extended until July 15, 1998, although late comments were accepted to the extent practicable. All comments received were considered in preparation of the final SWEIS[1]. DOE will utilize the analysis in this final SWEIS and prepare a Record of Decision on the level of continued operation of LANL. This decision will be no sooner than 30 days after the Notice of Availability of the final SWEIS is published in the *Federal Register*.

VOLUME II
MEASUREMENTS AND CONVERSIONS

The following information is provided to assist the reader in understanding certain concepts in this SWEIS. Definitions of technical terms can be found in volume I, chapter 10, Glossary.

SCIENTIFIC NOTATION

Scientific notation is used in this report to express very large or very small numbers. For example, the number 1 billion could be written as 1,000,000,000 or, using scientific notation, as 1×10^9. Translating from scientific notation to a more traditional number requires moving the decimal point either right (for a positive power of 10) or left (for a negative power of 10). If the value given is 2.0×10^3, move the decimal point three places (insert zeros if no numbers are given) to the right of its current location. The result would be 2,000. If the value given is 2.0×10^{-5}, move the decimal point five places to the left of its present location. The result would be 0.00002. An alternative way of expressing numbers, used primarily in the appendixes of this SWEIS, is exponential notation, which is very similar in use to scientific notation. For example, using the scientific notation for 1×10^9, in exponential notation the 10^9 (10 to the power of 9) would be replaced by E+09. (For positive powers, sometimes the "+" sign is omitted, and so the example here could be expressed as E09.) If the value is given as 2.0×10^{-5} in scientific notation, then the equivalent exponential notation is 2.0E-05.

UNITS OF MEASUREMENT

The primary units of measurement used in this report are English units with metric equivalents enclosed in parentheses.

Many metric measurements presented include prefixes that denote a multiplication factor that is applied to the base standard (e.g., 1 kilometer = 1,000 meters). The following list presents these metric prefixes:

giga	1,000,000,000 (10^9; E+09; one billion)
mega	1,000,000 (10^6; E+06; one million)
kilo	1,000 (10^3; E+03; one thousand)
hecto	100 (10^2; E+02; one hundred)
deka	10 (10^1; E+01; ten)
unit	1 (10^0; E+00; one)
deci	0.1 (10^{-1}; E-01; one tenth)
centi	0.01 (10^{-2}; E-02; one hundredth)
milli	0.001 (10^{-3}; E-03; one thousandth)

micro	0.000001 (10^{-6}; E-06; one millionth)
nano	0.000000001 (10^{-9}; E-09; one billionth)
pico	0.000000000001 (10^{-12}; E-12; one trillionth)

DOE Order 5900.2A, *Use of the Metric System of Measurement*, prescribes the use of this system in DOE documents. Table MC–1 lists the mathematical values or formulas needed for conversion between English and metric units. Table MC–2 summarizes and defines the terms for units of measure and corresponding symbols found throughout this report.

RADIOACTIVITY UNIT

Part of this report deals with levels of radioactivity that might be found in various environmental media. Radioactivity is a property; the amount of a radioactive material is usually expressed as "activity" in curies (Ci) (Table MC–3). The curie is the basic unit used to describe the amount of substance present, and concentrations are generally expressed in terms of curies per unit of mass or volume. One curie is equivalent to 37 billion disintegrations per second or is a quantity of any radionuclide that decays at the rate of 37 billion disintegrations per second. Disintegrations generally include emissions of alpha or beta particles, gamma radiation, or combinations of these.

RADIATION DOSE UNITS

The amount of ionizing radiation energy received by a living organism is expressed in terms of radiation dose. Radiation dose in this report is usually expressed in terms of effective dose equivalent and reported numerically in units of rem (Table MC–4). Rem is a term that relates ionizing radiation and biological effect or risk. A dose of 1 millirem (0.001 rem) has a biological effect similar to the dose received from about a 1-day exposure to natural background radiation. A list of the radionuclides discussed in this document and their half-lives is included in Table MC–5.

CHEMICAL ELEMENTS

A list of selected chemical elements, chemical constituents, and their nomenclature is presented in Table MC–6.

PART I
EXPANSION OF TA–54/AREA G LOW-LEVEL WASTE DISPOSAL AREA

I.1 ROLE OF THIS PROJECT-SPECIFIC SITING AND CONSTRUCTION ANALYSIS IN THE SITE-WIDE ENVIRONMENTAL IMPACT STATEMENT

This Project-Specific Siting and Construction (PSSC) analysis addresses the proposed expansion of the Area G low-level radioactive waste (LLW)[1] disposal area in Technical Area (TA)–54. It examines the siting and construction alternatives specific to this project in greater detail than the description and analysis presented in volume I of the Los Alamos National Laboratory (LANL) Site-Wide Environmental Impact Statement (SWEIS). The preferred alternative from this PSSC analysis is then included as one of the activities within the Expanded Operations Alternative discussed in volume I.

This arrangement of information and analysis allows the U.S. Department of Energy (DOE) to "zoom" in on aspects of this project that warrant more detailed description and analysis, while maintaining the clarity of volume I of the SWEIS. The siting and construction impacts of the Preferred Alternative described in this PSSC analysis are included along with the operational impacts described for the Expanded Operations Alternative in volume I to provide a complete understanding of the impacts of that alternative. Any differences in impacts that would be expected if a different PSSC alternative were selected are discussed in chapter 5 of volume I (section 5.3).

Waste volumes and strategies for managing the various waste streams are discussed in *Waste Management Strategies for LANL* (LANL 1998a) and chapter 5 (sections 5.2.9.3, 5.3.9.3, 5.4.9.3, and 5.5.9.3) of volume I, and are summarized in section I.1.1.3. Operations within the existing Area G, including new disposal cell excavation, are discussed in the *Description of Technical Areas and Facilities at LANL* (LANL 1998b) and in chapter 2 (sections 2.1.2.1 and 2.2.2.15) of the SWEIS, volume I.

More information regarding the approaches for disposal of LANL's wastes across the SWEIS alternatives (shipment off the site, storage on the site, and treatment) is presented in chapter 3 (sections 3.1, 3.2, 3.3, and 3.4) of volume I. The SWEIS analyzes continued disposal of LLW on the site within the Expanded Operations Alternative. The SWEIS also analyzes the LLW management strategy of storing the waste on the site for some short period and then shipping it off the site for disposal elsewhere, as part of the No Action, Reduced Operations, and Greener Alternatives.

The environmental impacts of operating the LLW disposal area and of the post-closure period are included in chapter 5 of volume I. The volume of disposal cells excavated, emissions to air, worker doses, and certain other parameters associated with LLW disposal operations would depend on the volume of LLW to be disposed of and not on the disposal location. The consequences to members of the public (especially post-closure), however, would depend on location because distance from the LLW disposal operation to the public depends on the location selected, and the

PSSC Alternatives for Expansion of Area G LLW Disposal

Develop Zone 4 at TA–54*—DOE would develop up to 24 acres (10 hectares) within Zone 4, which is immediately west of the existing active disposal area (see Figure I.2.5–1).*

Develop Zone 6 in TA–54*—DOE would develop up to 17 acres (7 hectares) within Zone 6, which is immediately to the west of Area L (Zone 5) and extends to Area J (see Figure I.2.5–1).*

Develop the North Site in TA–54*—DOE would develop up to 49 acres (20 hectares) within the North Site, which is immediately to the north of Zone 6 and Area J (see Figure I.2.5–1).*

Develop New Disposal Site at Another LANL TA*—DOE would establish a new LLW disposal facility at another location within LANL, presumed to be an undeveloped, undisturbed mesa. TA–67 is the specific TA examined as an example of the requirements and impacts associated with development of an undeveloped site for LLW disposal. The disposal site analyzed would develop up to 50 acres (20 hectares) plus roads and support areas at TA–67, which is located on Pajarito Mesa (see Figures I.1.1–1 and I.2.4.1–1).*

Preferred Alternative*—DOE's Preferred Alternative is to develop both Zones 4 and 6, proceeding westward in a step-by-step fashion from the existing footprint of Area G.*

magnitude of impacts decreases with distance. Post-closure impacts to the public are addressed for all alternative locations in chapter 5, section 5.3.3.5, of volume I.

In section I.2, this PSSC analysis identifies alternative locations at LANL where the additional LLW disposal capacity could be developed. Section I.2 also identifies alternative LLW management options not analyzed in this PSSC analysis because they are completely analyzed as part of the SWEIS alternatives in volume I. Section I.3 contains more detailed information about the environmental conditions at each of the alternative locations. Section I.4 presents the environmental consequences of development at each location. The SWEIS, including this PSSC analysis, is intended to provide a complete *National Environmental Policy Act of 1969* (NEPA) analysis of impacts regarding the proposed expansion of LLW disposal at LANL.

I.1.1 Background

DOE is considering the need to expand the LLW disposal area at LANL within the next 10 years. This PSSC analysis describes the alternatives for that development within LANL and their environmental consequences.

DOE and its predecessor agencies have operated LANL since 1943. Work at LANL produces LLW. Historically, DOE has disposed of this waste by burial in various designated sites within LANL. LANL's only currently active solid LLW disposal area is in the Material Disposal Area (MDA) G (referred to as Area G) at TA–54, shown in Figure I.1.1–1. TA–54 is located on Mesita del Buey, a narrow southeast-trending mesa about 2.5 miles (4 kilometers) long. Mesita del Buey is bordered by Cañada del Buey on the north and Pajarito Canyon on the south. San Ildefonso Pueblo land is located to the northeast of TA–54. The boundary between DOE land at TA–54 and San Ildefonso Pueblo land lies along the south edge of the top of the next mesa to the northeast of Cañada del Buey, an unnamed mesa south of Cedro Canyon. This boundary is about 650 feet (210 meters) northeast of the edge of Cañada del Buey at Area G.

Burial of LLW at TA–54, Area G, began in 1957 after the U.S. Atomic Energy Commission, with the assistance of the United States Geological Survey (USGS), selected

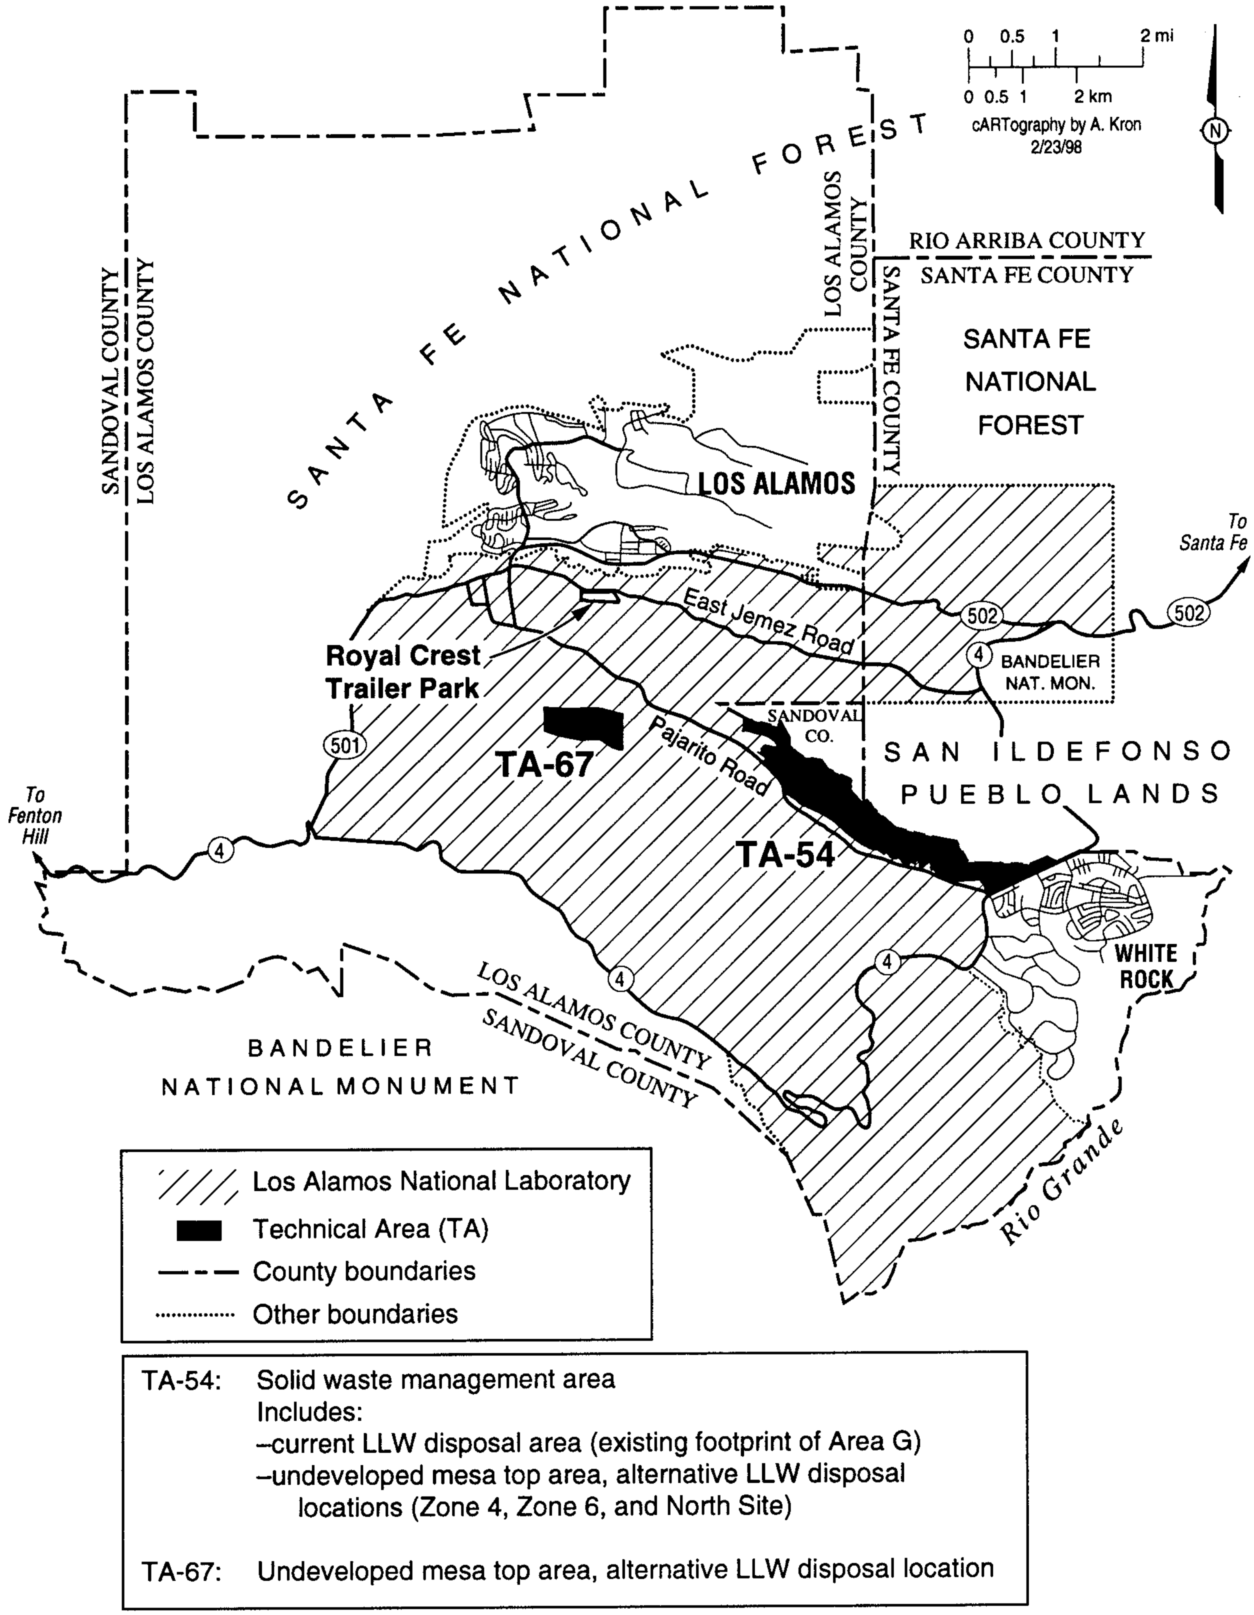

FIGURE I.1.1–1.—*Location of LANL, TA–54, and TA–67.*

Mesita del Buey as the disposal site for LANL's LLW. Area G was described in a historical report as one of the on-site land disposal facilities for radioactive wastes (Rogers 1977).

The previous (1979) SWEIS identified all of Mesita del Buey as an area for handling operational solid waste, including radioactive waste (DOE 1979). The 1979 SWEIS states, "The radioactive disposal area in use is Area G, located on Mesita del Buey. The dedicated waste disposal area contains a total of about 80 acres (32 hectares) of which approximately 37 acres (15 hectares) has been in active use since 1958. Based upon current waste generation rates, this area should provide an additional 15 or more years use. However, since the entire Mesita del Buey has been designated for the handling of operational solid waste, there will still be another 23 acres available for use beyond that time" (DOE 1979).

The original LLW disposal area at Area G was expanded once to reach its current size of 63 acres (25 hectares). This active area was referred to in the 1979 SWEIS as the "existing footprint." Waste management facilities at Area G include LLW disposal cells and shafts, a 200-ton (180-metric ton) compactor for LLW, soil-covered asphalt pads containing stacks of waste drums, temporary tension domes used to store drums of transuranic (TRU) waste[2] and low-level radioactive mixed waste[3] (LLMW), and a monofill disposal cell (a disposal cell containing a single waste type) for asbestos that has radioactive contamination.

A detailed description of the LLW streams and estimates of the volumes that might be produced under each of the SWEIS alternatives is provided in *Waste Management Strategies for LANL* (LANL 1998a) and chapter 5 of the SWEIS, volume I. Descriptions of the techniques by which LLW disposal cells are constructed, filled, and closed are found in the *Detailed Operating Procedure* (DOP) *54G–013*, (LANL 1996a). This DOP incorporates recommendations made by USGS (cited in Rogers 1977 and in Purtymun et al. 1980) and others (Koopman 1965) on disposal cell placement with regard to distances from canyon walls and bottoms. The Performance Assessment describes closure and post-closure requirements for the existing Area G (LANL 1998f).

I.1.1.1 *History of Expansion Plans at Area G*

Given the limited area within the existing footprint at Area G, DOE and LANL waste management personnel have recognized for several years the need to consider additional areas at LANL that would be suitable for burial of LLW (LANL 1982). The part of Mesita del Buey immediately to the west of Area L (Figure I.1.1.1–1) received the first and most thorough investigation because it is contiguous with the existing footprint and is within the area designated in 1957 for solid waste management operations. Expansion to Area L was regarded as logical but not imminent at the time the previous SWEIS was issued (DOE 1979). Specific planning and siting for the next LLW disposal area began about 1989.

I.1.1.2 *History of NEPA Reviews*

On October 20, 1990, DOE directed that NEPA review of an expansion of existing Area G be prepared. By 1994, no draft was considered ready for preapproval public review, in part because of questions about the need, arising from uncertainties in decontamination and decommissioning and environmental

2. TRU wastes contain a radionuclide with a half-life greater than 20 years and alpha activity of 100 nanocuries per gram (nCi/g) or greater at the time of measurement, excluding naturally occurring and depleted uranium, spent nuclear fuel, and high-level waste.

3. LLMW contains LLW, plus chemicals regulated as hazardous under the *Resource Conservation and Recovery Act* (RCRA) (42 United States Code [U.S.C.] §6901).

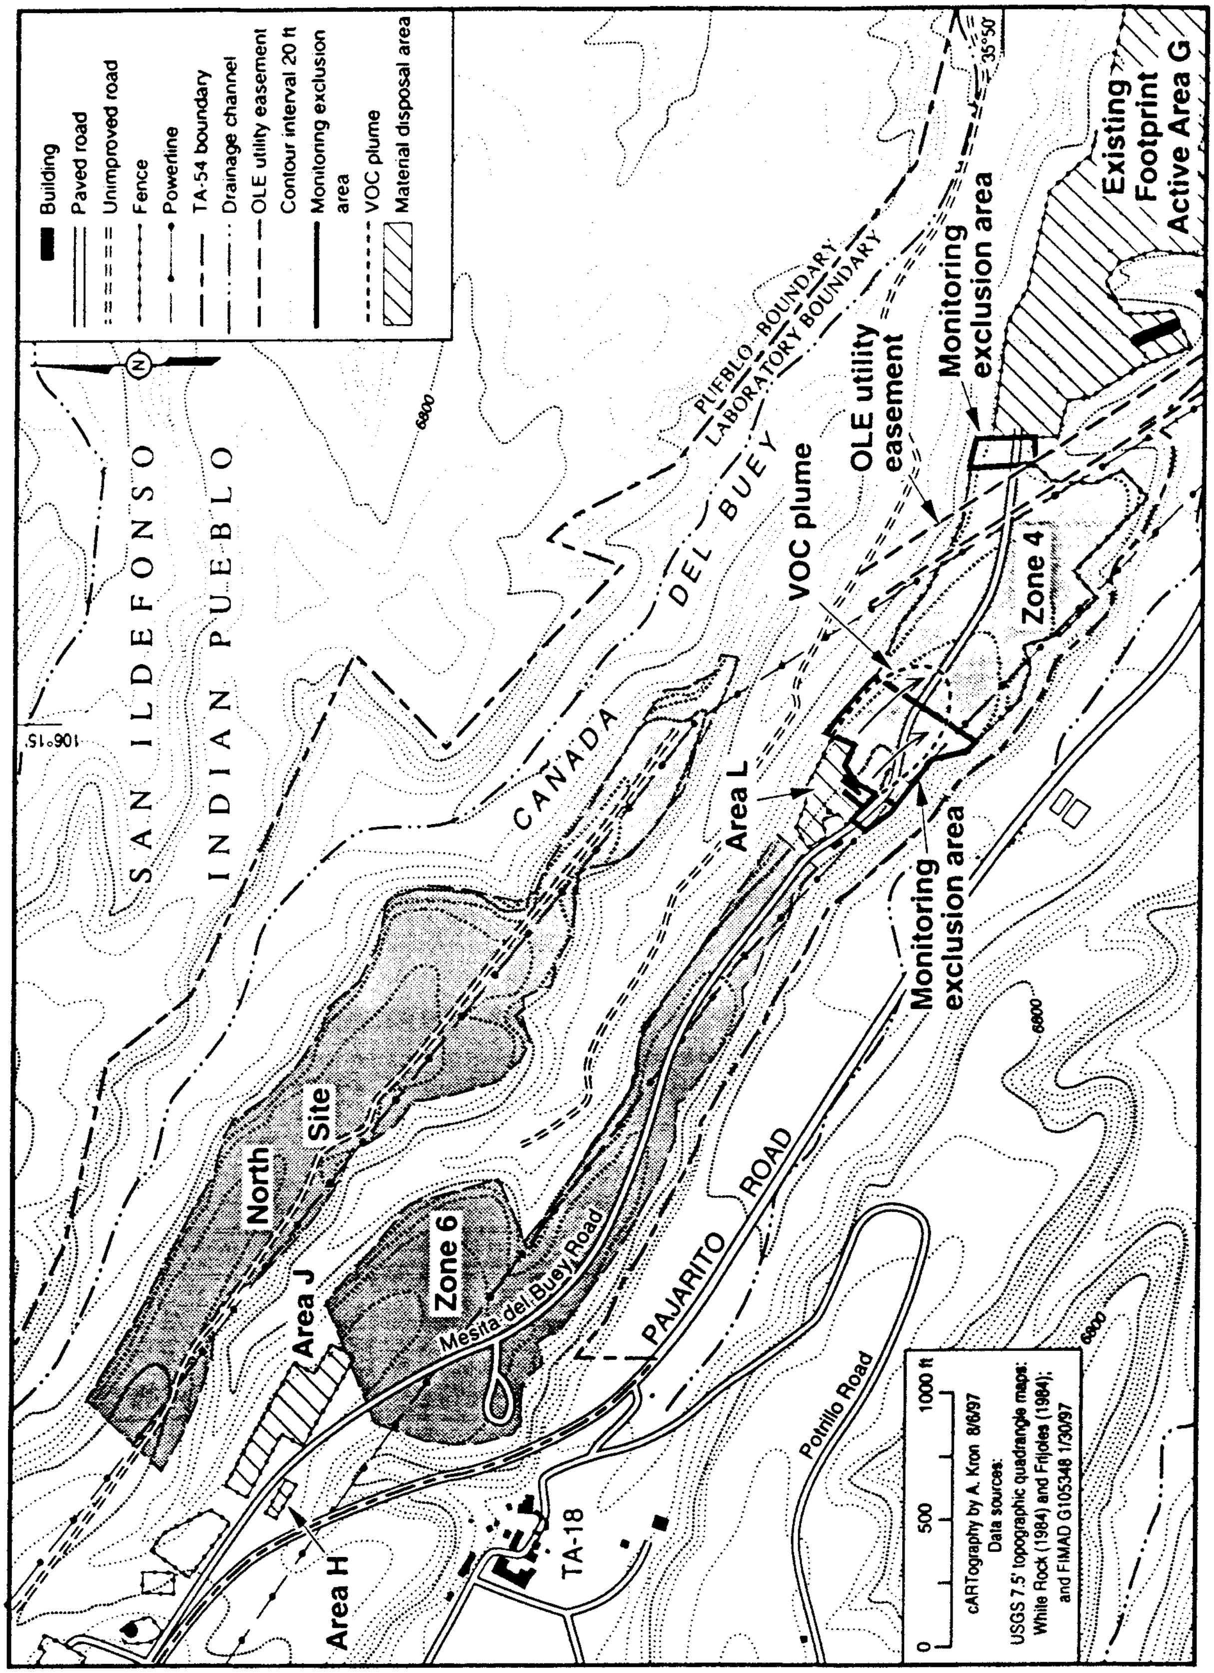

FIGURE I.1.1.1–1.—*Location Within TA–54 of Zones 4 and 6, Areas H, J, and L, and North Site.*

restoration (ER) waste volume projections. Several of the unresolved questions were discussed in a report prepared by a group named Our Common Ground (OCG 1993). (This was an unofficial group of LANL employees and members of the surrounding community that were asked by the LANL Director in 1993 to review the proposal for expansion of Area G.) In August 1994, the Advance Notice of Intent (NOI) to prepare a new SWEIS was published in the *Federal Register* (FR). Further development of disposal capacity outside the existing Area G footprint was specifically suggested for coverage in the new SWEIS. The NOI published in the FR on May 12, 1995 (60 FR 25697), made the commitment to include the NEPA review for this proposal in the SWEIS.

I.1.1.3 *Low-Level Radioactive Waste Generation and Anticipated Disposal Requirements at LANL*

Operations at LANL will continue to generate LLW that requires disposal by DOE. Waste volumes during the 10-year SWEIS timeframe will increase significantly over volumes generated in recent years (1990 through 1994). This increase stems primarily from clean-up projects planned under the ER Project. The assumptions used here are that the volume of LLW would vary by the SWEIS alternative, that regardless of alternative at least some of the LLW generated would be disposed of in disposal cells (trenches)[4] at Area G, and that the remaining LLW would need to be disposed of off site (except under the Expanded Operations Alternative, when on-site disposal capacity is expanded and all LLW is disposed of on site). The projected volumes of LANL's LLW by SWEIS alternative are summarized in Table I.1.1.3–1[5]. There is insufficient space within existing Area G to accommodate all LLW anticipated from LANL activities in the next 10 years, regardless of alternative.

4. LLW with high surface activity, tritium-contaminated LLW, and some other special wastes are disposed of in shafts drilled into tuff. There is sufficient space in the existing footprint to meet the 10-year shaft disposal requirements.

5. Volumes shown in tables in this document are presented in metric units (cubic meters) because this is the form used in volume I of the SWEIS, the *Waste Management Programmatic Environmental Impact Statement* (WM PEIS) (DOE 1997), and other documents on this subject. Also, exponential notation is used; 10^3 means "thousand."

TABLE I.1.1.3–1.—*LANL's LLW Volume to be Disposed of in Next 10 Years, by SWEIS Alternative (10^3 cubic meters)[a]*

LLW CATEGORY	NO ACTION	EXPANDED OPERATIONS	REDUCED OPERATIONS	GREENER
LLW Generated[a]	95	117	84	97
LLW to be Disposed[b]	88	112	78	90
Currently Developed Area G Capacity	36	36	36	36
Waste Volume Above Currently Developed Area G Capacity[c]	52	76	42	54

[a] From volume I of the SWEIS, chapter 5 (sections 5.2.9.3, 5.3.9.3, 5.4.9.3, and 5.5.9.3).
[b] Volume after compaction and other treatments.
[c] Under the No Action, Reduced Operations, and Greener Alternatives, much of the waste volume would be shipped off the site for disposal. Under Expanded Operations, on-site disposal capacity would be expanded, and the waste would be disposed of on the site (volume I, chapter 3).

The volume of LLW disposal space that can be developed within the existing Area G is uncertain because the best terrain has been used. The excavated but unfilled disposal cell volume is 34,000 cubic yards (26,000 cubic meters). The surface of the remaining area is sloped and the subsurface features are unknown. New disposal cell volume is estimated at 13,000 cubic yards (10,000 cubic meters) but could be less.

In addition, in the final *Waste Management Programmatic Environmental Impact Statement* (WM PEIS) (DOE 1997), the Preferred Alternative for LLW designates LANL as one of six candidate sites from which DOE will choose two or three regional LLW disposal sites (DOE 1997)[6]. The options under which LANL may receive off-site LLW and the projected volumes are shown in Table I.1.1.3–2.

6. In addition, the WM PEIS Preferred Alternative for LLMW designates LANL as one of six candidate sites, from which DOE will choose two or three regional disposal sites. LANL does not currently dispose of such waste at Area G or elsewhere. If LANL is chosen as a regional disposal site for LLMW, the site-specific impacts of such disposal would be addressed in further NEPA review, tiered from the WM PEIS and this SWEIS.

DOE's decisions within the context of the WM PEIS are independent of the SWEIS but may, in and of themselves, force expansion of Area G. A reasonably foreseeable future and bounding case would be a combination of the WM PEIS Preferred Alternative—Regionalized (Regionalized 3, 4, 5) with the Expanded Operations Alternative in LANL's SWEIS, whereby the 10-year shortfall of LLW disposal space at LANL would be about 125,000 cubic yards (96,000 cubic meters). Such a decision from the WM PEIS would represent a substantial change in the approach to LLW disposal at LANL. This would be a long-term commitment (beyond the 10-year period addressed in the SWEIS) by DOE to utilize space at LANL as a regional LLW disposal site. (If LANL is chosen as a regional disposal site for LLW, the site-specific impacts of that decision would be addressed in further NEPA review tiered from the WM PEIS and this SWEIS.) Alternatively, DOE could decide to ship all LANL's LLW to one of the other regional disposal sites. (As discussed above, shipment of LANL's LLW for off-site disposal is analyzed in the No Action, Reduced Operations, and Greener Alternatives.)

TABLE I.1.1.3–2.—*Bounding LLW Volumes to be Disposed at LANL, Including LLW Potentially Shipped to LANL Based on WM PEIS over 10 Years (10^3 cubic meters)*

WM PEIS ALTERNATIVE	REGIONALIZED 1, 2	PREFERRED ALTERNATIVE: REGIONALIZED 3, 4, 5[a]	CENTRALIZED 3, 4
Off-Site LLW Volume for Disposal at LANL[b]	16	20	3
LANL LLW to be Disposed[c]	112	112	112
Maximum LLW Volume for Disposal at LANL	128	132	115
Available Capacity in Area G	36	36	36
Shortfall in Capacity at Area G	92	96	79

[a] The Preferred Alternative for LLW disposal in WM PEIS is regionalized, with LANL as a candidate for one of the two or three disposal sites for the complex.
[b] From Appendix I, Table I.3–4, WM PEIS (DOE 1997), adjusted to 10 years.
[c] Maximum volume, Expanded Operations Alternative, from Table I.1.1.3–1.

There are several sources of uncertainty in predictions about volume of the LLW to be disposed of at LANL over the next 10 years. One source of uncertainty is in predictions of waste to be generated at LANL under the four SWEIS alternatives. Although operations-related LLW volumes are reasonably predictable given the levels of operations, the volume of LLW to be produced by ER and decontamination and decommissioning activities is potentially very large but is tied to the level of funds allocated annually by DOE for the clean-up programs. The *Waste Management Strategies for LANL* LLW volume projections have been used here because they are bounding cases that include both operational and ER/ decontamination and decommissioning LLW estimates (LANL 1998a). This waste volume estimating method responds to one of the issues raised in the report by Our Common Ground (OCG 1993).

The volume of additional LLW disposal space needed over the next 10 years and into the future is not known at present. DOE's options to ship LLW from other locations for disposal at LANL, as developed in the WM PEIS, introduce another uncertainty into the space needed for LLW disposal.

This PSSC analysis presents various alternative locations at LANL that could be developed for LLW disposal. To preserve flexibility and as a bounding case for the next 10 years, this PSSC analysis assumes the LLW volume to be accommodated is that described for the SWEIS Expanded Operations Alternative (146,000 cubic yards [112,000 cubic meters]) from the *Waste Management Strategies for LANL* and in chapter 5 (section 5.3.9.3) of the SWEIS, volume I, plus the maximum quantity of LLW proposed to be moved to LANL from other DOE locations over 10 years (26,000 cubic yards [20,000 cubic meters]), as described in the WM PEIS (DOE 1997). The remaining 47,000 cubic yards (36,000 cubic meters) of disposal space in the existing footprint at Area G will be used prior to expansion of on-site LLW disposal capacity. Over the next 10 years, DOE could need to develop additional disposal space at LANL for up to 125,000 cubic yards (96,000 cubic meters) of LLW (the greatest foreseeable disposal capacity shortfall, as reflected in Table I.1.1.3–2).

I.2 ALTERNATIVES

This section identifies alternative locations that DOE could develop as disposal cells (trenches) to dispose of LLW that would be generated at LANL over the next 10 years, plus LLW that might be shipped to LANL for disposal from other DOE locations. This discussion is focused on construction and development of new LLW disposal areas. (Figures I.1.1–1 and I.1.1.1–1 illustrate the locations being considered.) Alternatives discussed include:

- Develop Zone 4 at TA–54.
- Develop Zone 6 at TA–54.
- Develop the North Site at TA–54.
- Develop an undisturbed site at another LANL TA. (TA–67 is used as an example.)
- Develop both Zones 4 and 6 in step-wise fashion (the Preferred Alternative).

Each of the five alternatives could provide more than enough space for potential LLW disposal needs (125,000 cubic yards [96,000 cubic meters]) for the next 10 years (Table I.1.1.3–2). The differences among alternatives follow from consequences of development at the different locations. The alternative of developing at an undisturbed location responds to one of the issues raised in the report by Our Common Ground (OCG 1993).

Additional alternatives for LLW management are not analyzed in detail in this PSSC analysis because they are analyzed within the SWEIS itself. The typical No Action Alternative (i.e., to continue burying LLW within the existing footprint at Area G) is discussed in chapter 3 of volume I as a part of normal operations; its consequences are presented in chapter 5. This activity is common to all the SWEIS alternatives up to the point that on-site disposal ends (for the No Action, Reduced Operations, and Greener Alternatives). Shipping LLW off the site for disposal elsewhere is a part of the SWEIS No Action, Reduced Operations, and Greener Alternatives, but not the Expanded Operations Alternative.

I.2.1 Develop Zone 4 at TA–54

Under this alternative, DOE would develop Zone 4 within Area G, immediately west of the active disposal area as shown in Figure I.1.1.1–1, for the additional LLW disposal capacity. The Zone 4 area is about 30 acres (12 hectares), but some of the area could not be developed for disposal cells because of groundwater monitoring wells and a utility easement. Two options will be discussed for developing Zone 4, the area north of the current road and the entire area, both north and south of the road. Developing just the area north of the road would avoid archaeological sites. Although the area to the south of the road is larger, it would be impractical to develop just that area because of the archaeological sites located there.

I.2.1.1 *Location Description*

Zone 4 is located on Mesita del Buey, within TA–54 (Figures I.1.1–1 and I.1.1.1–1). The upper portion of Mesita del Buey is of Bandelier Tuff. The Bandelier Tuff is composed primarily of volcanic ash. The tuff is a good material in which to dispose of LLW because it forms a natural barrier to fluid migration, primarily because of its generally low hydraulic conductivity (Purtymun and Kennedy 1971 and Rogers 1995). No geologic faults have been identified at Mesita del Buey.

Zone 4, an area of slightly less than 30 acres (12 hectares), runs westward from the existing footprint of Area G to Area L, where chemical wastes are managed. This area is fenced, and access is controlled by the gate at the westernmost end of the waste management area. The paved Mesita del Buey Road runs the length of the mesa into the developed area. The area is level and covered with second-growth pinyon[7] and juniper and an understory of shrubs and grasses. Zone 4 is within the foraging area of a peregrine falcon nest site, a site that has been unoccupied in recent years.

There are some constraints on developing LLW disposal space in Zone 4. Because Area L was once used for chemical waste disposal, there is a volatile organic compound (VOC) plume in the subsurface. LANL set aside monitoring exclusion zones on either side of Zone 4 to track the movement of the VOC plume. At the western edge of Zone 4, the monitoring zone is about 3 acres (1.2 hectares), and the eastern monitoring zone is about 1 acre (0.4 hectares). These features are shown in Figure I.1.1.1–1. The VOC plume is being monitored and has not moved appreciably in about 5 years. It extends in the pore gas space about 500 feet (150 meters) eastward into Zone 4 (LANL 1994). The organic compound of maximum concentration is 1,1,1-trichloroethane (TCE), at 5,540 parts per million (ppm), as detected in 1997 (LANL 1998e). The identity and concentrations of VOCs are listed in appendix I.B. A study of the human health risk posed by this plume will be performed under the ER Project at LANL during the 1997 to 1999 timeframe. Until the results are known, excavations will not be made in these exclusion zones. If disposal cells were to be excavated, administrative controls such as monitoring the air in the breathing area and supplying workers with respiratory protection could protect worker health.

---

7. A cross-reference between the common and scientific names of the plants and animals noted in the text is found in appendix I.A.

Very small but measurable amounts of VOCs are being released into the atmosphere as a consequence of the VOC plume. Any effects that these emissions are having on fossorial (digging) animals as well as other area plants and animals are being assessed through ecological risk assessments.

An easement for the proposed Public Service Company of New Mexico (PNM) Ojo (Transmission) Line Extension (OLE) passes through this end of Zone 4; but, plans to construct the OLE have been suspended indefinitely. The need for additional electrical power at LANL has not been resolved yet. This easement area would be avoided until the electrical supply issue is settled.

Nine cultural resources, remains of prehistoric Native American habitation, have been identified within Zone 4. All except one is south of Mesita del Buey Road. The exception is located north of the road but within the ER monitoring zone. The site would not be excavated because this monitoring zone would not be disturbed. As discussed further in section I.3.6, an archeological data recovery plan has been approved by the New Mexico State Historic Preservation Office(r) (SHPO) for the sites in Zone 4 that are eligible for the National Register of Historic Places (NRHP). At Zone 4, the boundary of San Ildefonso Pueblo is 1,300 feet (400 meters) northeast of the north edge of the top of Mesita del Buey (Figure I.1.1.1–1). The traditional cultural property (TCP) study conducted for the SWEIS did not identify any TCPs in this area.

I.2.1.2 *Development*

If this alternative were implemented, a radiation control and monitoring zone would be placed adjacent to an active disposal cell so that waste disposal crews could be monitored as they prepared to leave the area. A decontamination facility, probably an impervious wash pad capable of accommodating a truck, would be added if needed. Decontamination water would be collected and transferred to the Radioactive Liquid Waste Treatment Facility (RLWTF) at TA–50. These facilities would be connected to the existing utility lines. In addition, an air monitoring network would be installed. The existing waste management support facilities and infrastructure within the existing footprint area would continue to be used. No new roads or utilities would be required. The trees in the area, mainly pinyon and juniper, would be removed and the wood would be chipped and burned or used as mulch on the site (as discussed in section I.4.1.2).

DOE has identified two options for developing LLW disposal areas within Zone 4. Just the area to the north of Mesita del Buey Road could be developed, or the areas on both the north and south sides of the road could be developed together. Several archaeological sites would have to be excavated in order to proceed with development south of the road. If additional disposal area was limited to the north side of the road, avoiding the monitoring zones, no archeological sites need be excavated, and the VOC monitoring apparatus would not be disturbed. Engineering and administrative controls could be put in place to mitigate the potential for radiological contamination of archeological sites to the south of the road.

If the area on the both sides of Mesita del Buey Road were developed, the eight archaeological sites to the south of the road would be affected. Excavating waste disposal cells among unexcavated archaeological sites is not feasible for several reasons. Fencing around the surface features would reduce but not prevent the chance of their being run over by heavy excavation equipment and waste delivery trucks. The extent of a site cannot be accurately determined from remaining surface features alone, and the equipment used to excavate disposal cells (back hoe and front-end loader) could destroy subsurface features. Avoiding archaeological sites would greatly reduce the potential disposal volume per acre, thus expanding the number of acres needed for a dedicated LLW disposal area. Finally, there are concerns about the possibility of contamination migrating into the archaeological sites from buried radioactive wastes.

The areas that would be disturbed are summarized in Table I.2.1.2–1. The estimate of usable acreage takes into account the requirement for disposal cells to be 50 feet (15 meters) from the competent canyon wall (Rogers 1977 and Purtymun et al. 1980), avoiding the VOC plume, monitoring areas, and the OLE easement. The long-term impacts of disposal at this location were assessed in the Area G Performance Assessment (LANL 1998f) and are discussed further in volume I (section 5.3.3.5).

I.2.2 Develop Zone 6 at TA–54

Under this alternative, DOE would develop the area of Mesita del Buey that lies within TA–54 immediately to the west of Area L (Zone 5) and extends to Area J for the additional LLW disposal capacity. This area, referred to as Zone 6, is slightly less than 40 acres (16 hectares). The location is shown in Figure I.1.1.1–1. The location is not fenced, but access by road is controlled by the same gate referred to in section I.2.1.1.

I.2.2.1 *Location Description*

The soil and underlying tuff at Zone 6 are the same as those described for Zone 4 in section I.2.1.1.

The area is level and covered with second-growth pinyon and juniper and an understory of shrubs and grasses. The mesa top is quite narrow in part of this location, and Mesita del Buey Road runs down the middle of the mesa. These features would make about half the surface area difficult and inefficient to develop as disposal cells. Zone 6 is also within the foraging area of the peregrine falcon nest site noted in section I.2.1.1. Monitoring data indicate the presence of no ER locations. There are seven archaeological sites within Zone 6 that could be affected. Prior to developing this area, a recovery plan would be prepared, and the SHPO would be consulted. At Zone 6, the boundary of San Ildefonso Pueblo lies about 1,600 feet (500 meters) northeast of the north edge of the top of Mesita del Buey (Figure I.1.1.1–1). The TCP study conducted for the SWEIS did not result in the identification of specific TCPs in Zone 6.

I.2.2.2 *Development*

If this alternative were implemented, the same steps would be implemented as those discussed in section I.2.1.2. No new roads or utilities

TABLE I.2.1.2–1.—*Low-Level Waste Disposal Areas Within Zone 4 of TA–54*

OPTION	APPROXIMATE AREA DISTURBED	APPROXIMATE WASTE VOLUME (10^3 m^3)[a]
Option 1 – Designate approximately 7 acres (3 hectares) west of the existing footprint and east of the existing ER monitoring area as an MDA, north of the Mesita del Buey access road only.	7 acres (3 hectares)	260
Option 2 – Designate approximately 30 acres (12 hectares) west of the existing footprint and east of the existing ER monitoring zone as an MDA, both sides of Mesita del Buey access road.	24 acres (10 hectares)	800

[a] Waste capacity value calculated assuming disposal cell depth of 65 feet (20 meters) and a 40 percent fill efficiency.

would be required, but the present road could be relocated nearer to the canyon rim to free more contiguous space for disposal cell development. Here, fencing would not be placed around the entire zone; only the disposal cells being excavated and filled with LLW would be fenced. This fencing would prevent people and medium- to large-sized animals from entering open disposal cells. Fencing would be removed after the disposal cells are closed.

The trees in the mesa-top area, mainly pinyon and juniper, would be removed as necessary and managed as discussed in section I.2.1.2.

Zone 6 presents some constraints on efficient development because much of the area is located along a narrow part of the mesa. In the narrow area, it would be difficult to site disposal cells with the required 50 feet (15 meters) set back from the mesa edges and still avoid Mesita del Buey Road. Most of the disposal cells would be placed in the wider area at the west end of Zone 6. The area that could be disturbed and potential waste volume are shown in Table I.2.2.2–1.

While this site was not specifically analyzed regarding the long-term impacts of waste disposal at this location, the site characteristics at Zone 6 are essentially identical to those analyzed in the Area G Performance Assessment (LANL 1998f). Thus, the results of the Performance Assessment (discussed further in volume I, chapter 5, section 5.3.3.5) are considered to be applicable to this location (Newell 1998).

TABLE I.2.2.2–1.—*LLW Disposal Area Within Zone 6 of TA–54*

OPTION	APPROX. AREA DISTURBED	APPROX. WASTE VOLUME (10^3 m^3)
Designate 40 acres (16 hectares) Immediately West of Area L as an MDA	17 acres (7 hectares)	550

Waste capacity value calculated assuming disposal cell depth of 65 feet (20 meters) and a 40 percent fill efficiency.

I.2.3 Develop the North Site, TA–54

Under this alternative, DOE would develop the northern finger of Mesita del Buey that lies within TA–54 immediately to the north of Zones 6 and Area J for the additional LLW disposal capacity. The area is shown in Figure I.1.1.1–1. The mesa top in this area is undeveloped and relatively undisturbed. A 115-kilovolt electrical power line and an unimproved road run down its length. The location is not fenced, and access is not controlled. This area will be referred to in this document as the North Site, TA–54. The total area is about 63 acres (25 hectares), but not all is developable for disposal cells.

I.2.3.1 *Location Description*

The soil and underlying tuff at the North Site are the same as those described for Zone 4 in section I.2.1.1.

The mesa top at the North Site has an area suitable for disposal cell development of about 49 acres (20 hectares). The area is very similar to Zones 4 and 6, described in sections I.2.1.1 and I.2.2.1. At the North Site, the boundary of San Ildefonso Pueblo is about 300 feet (90 meters) northeast of the north edge of the top of Mesita del Buey (Figure I.1.1.1–1). The TCP study conducted for the SWEIS did not result in the identification of specific TCPs at the North Site.

Four archaeological sites are known to be present within the North Site, but the area has not been as rigorously surveyed as has the rest of Mesita del Buey. Additional sites may be present. Prior to developing this area, a recovery plan would be prepared and the SHPO would be consulted. No ER locations have been identified.

I.2.3.2 *Development*

If this alternative were implemented, the development would be the same as presented for Zone 6 (section I.2.2.2), except that the unpaved road down the mesa would be upgraded by topping it with asphalt. The support structures at Area G would continue to be used as the management center. However, due to the distance from the developed part of Mesita del Buey, some utility lines, including a 110/220-volt electrical line and telephone lines, may be installed aboveground. A decontamination facility, probably an impervious wash pad capable of accommodating a truck, could be added if needed. Decontamination water would be collected and transferred to the RLWTF by tank truck or through the existing pipeline from Area G. Here, fencing would not be placed around the entire zone; only the disposal cells being excavated and filled with LLW would be fenced. This fencing would prevent people and animals from entering open disposal cells. Fencing would be removed after the cells are closed.

The trees in the mesa top area, mainly pinyon and juniper, would be removed as needed and managed as discussed in section I.2.1.2.

The North Site may present some constraints on efficient development. A 115-kilovolt utility line runs the length of the mesa. Current practice precludes disposal cell construction under electrical lines for safety reasons. The electrical line could be relocated toward the edge of the mesa to maximize disposal space. In addition, the USGS specification is that the bottom of the disposal cell be a minimum of 10 feet (3 meters) above the adjacent canyon bottom; this limits the allowable depth of the disposal cells and requires longer or wider disposal cells to accommodate a given volume of waste. The acreage disturbed under this alternative takes this constraint into account.

While this site was not specifically analyzed regarding the long-term impacts of waste disposal at this location, the site characteristics at the North Site are essentially identical to those analyzed in the Area G Performance Assessment (LANL 1998f). Thus, the results of the Performance Assessment (discussed further in volume I, chapter 5, section 5.3.3.5) are considered to be applicable to this location (Newell 1998).

The potential area disturbed and approximate waste volume are summarized in Table I.2.3.2–1.

TABLE I.2.3.2–1.—*Low-Level Waste Disposal Area Within the North Site of TA–54*

OPTION	APPROX. ACREAGE DISTURBED	APPROX. WASTE VOLUME (10^3 m^3)
Designate 63 acres (25 hectares) Immediately North of Zone 6 and Area J as an MDA	49 acres (20 hectares)	1,600

Waste capacity value calculated assuming disposal cell depth of 65 feet (20 meters) or 10 feet above the adjacent canyon bottom (whichever is less) and a 40 percent fill efficiency.

I.2.4 Develop New Disposal Site at Another LANL Technical Area (TA–67)

Under this alternative, DOE would establish a new LLW disposal facility at another unspecified location at LANL. The new area is assumed to be an undeveloped, undisturbed mesa, not adjacent to the existing LLW disposal area. This alternative would require that the existing facilities at Area G be duplicated in another location at LANL. A good deal of information is known about Pajarito Mesa within TA–67 because this area was evaluated as a possible location for a mixed waste disposal facility, a proposal subsequently canceled. This location was chosen as an example of requirements for developing undeveloped mesas within LANL for LLW disposal. Other undeveloped mesa-top locations would present similar but not necessarily identical requirements for development (i.e., not all mesa tops are within potential habitat of threatened and endangered [T&E] species or possible existence of a fault, but virtually all contain archaeological sites).

I.2.4.1 *Location Description*

The representative undeveloped location selected is TA–67 on Pajarito Mesa because it is the best characterized area on an undeveloped mesa. This location is shown in Figures I.1.1–1 and I.2.4.1–1.

The upper portion of Pajarito Mesa is also of Bandelier Tuff, the properties of which are described in section I.2.1.1. Beneath TA–67, the tuff is a 295-foot (90-meter) thick bed of Bandelier Tuff (Broxton and Chipera 1994). The underlying layer is also of older sedimentary deposits and basalt flows. The Rendija Canyon fault may underlie the western portion of TA–67. (See chapter 4, section 4.2.2.2, Figure 4.2.2.2–1).

TA–67 is an undeveloped area of slightly less than 72 acres (29 hectares) atop Pajarito Mesa. To the north of the mesa lies Pajarito Canyon; to the south is Threemile Canyon. The mesa top is level and covered with ponderosa pine, pinyon, and juniper with an understory of shrubs and grasses. The site is within the buffer zone of a high explosives (HE) research and development area. It is also within the blast circles for active HE firing sites at TA–15 and TA–40 (LANL 1991). The blast circle defines an area wherein fragments from tests may fall and from which humans are excluded during tests. Access to TA–67 at present is via West Jemez Road (State Route 501) and then through a security gate via Anchor Ranch Road and east on R-Site Road.

TA–67 is within one-quarter mile of potential nesting habitat for the Mexican spotted owl, and is within potential roosting and foraging habitat for that species.

There are 11 cultural resources within TA–67 that might be affected by development of the site (LANL 1998c). The TCP study conducted for the SWEIS did not identify any specific TCPs in the area. The boundary of San Ildefonso Pueblo is about 1.5 miles (2.4 kilometers) east of TA–67 (Figure I.1.1–1).

I.2.4.2 *Development*

If this alternative were implemented, a set of waste management support facilities and infrastructure similar to that in the existing footprint area would be constructed and installed at TA–67, including office structures, personnel showers, equipment and supply storage lockers, control rooms, personnel monitoring stations, and the surface decontamination wash pad and structures. It would not be efficient to continue to use the support facilities at Area G because of the distance. Decontamination water would be collected in a tank and moved by tank truck to the RLWTF. Another 200-ton (180-metric ton) compactor may be installed, or the existing unit might be relocated. The infrastructure (consisting of roads, utility lines, and air monitoring network) would have to be installed. An access control gate and some fencing would be installed. The access road would require either a bridge over Threemile Canyon or an access road around the west end of the canyon. The installation in the existing footprint would remain active while the new location was being developed.

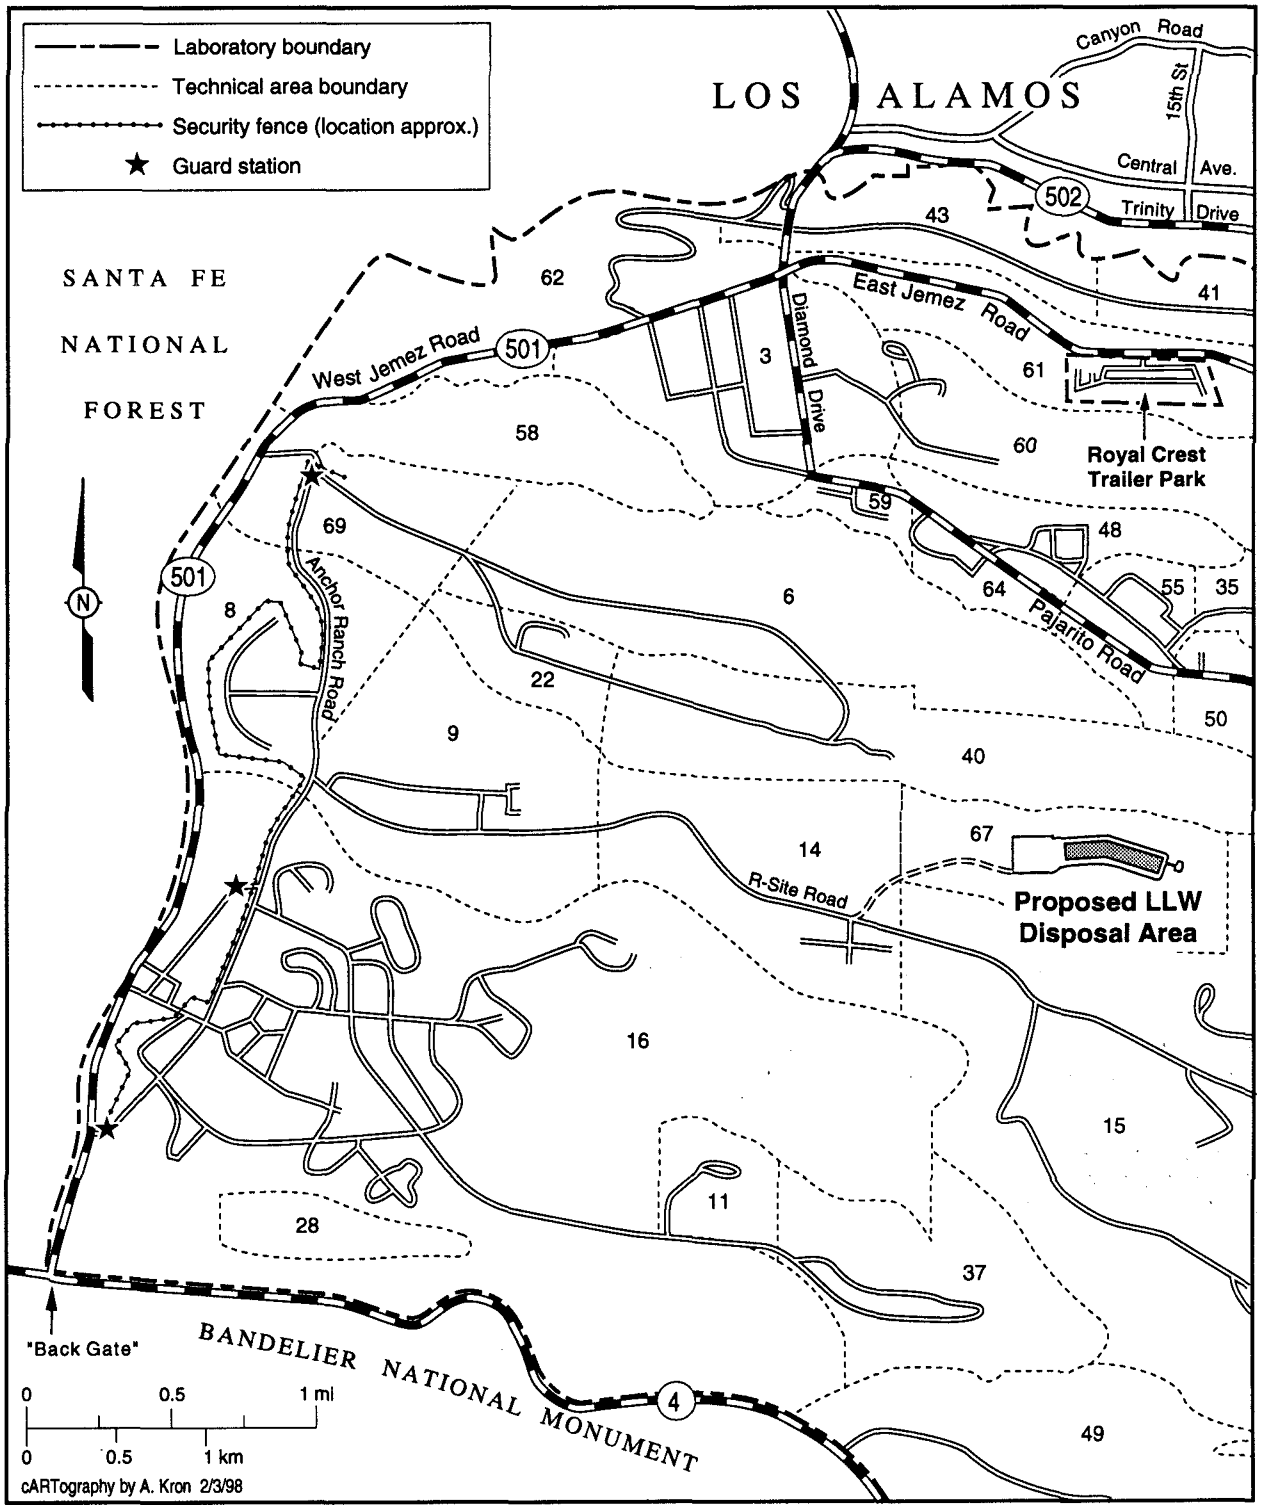

FIGURE I.2.4.1–1.—*Location of the Proposed LLW Disposal Area at TA–67.*[1]

[1] The TA numbers are included.

The trees in the mesa-top area, ponderosa pines, pinyons, and juniper, would be removed and managed as discussed in section I.2.1.2. The surface contour would be changed as needed to control runoff and protect the wetland north of the mesa. A data recovery plan would be developed, archaeological sites would be excavated as necessary, and data would be recovered, as discussed in sections I.3.6 and I.4.4.5.

Fencing would not be placed around the entire zone; only the disposal cells being excavated and filled with LLW would be fenced. This fencing would prevent people and animals from entering open cells. Fencing would be removed after the disposal cells are closed.

About 50 acres (24 hectares) is assumed for waste disposal cells, while the remainder of the area disturbed would be for roads and other infrastructure development. The potential area disturbed and waste volume are summarized in Table I.2.4.2–1.

While this site was not specifically analyzed regarding the long-term impacts of waste disposal at this location, the site characteristics at TA–67 (and many other mesa tops in the area) are sufficiently similar to those analyzed in the Area G Performance Assessment (LANL 1998f) in that the Performance Assessment results (discussed in volume I, chapter 5, section 5.3.3.5) are considered applicable to other mesa-top locations, such as TA–67 (Newell 1998). It is important to note that the possible existence of a fault beneath part of the TA–67 site introduces additional issues that do not exist at TA–54.

TABLE I.2.4.2–1.—*LLW Disposal Area Within TA–67*

OPTION	APPROX. ACREAGE DISTURBED	APPROX. WASTE VOLUME (10^3 m^3)
Designate 72 acres (29 hectares) at TA–67 on Pajarito Mesa as an MDA	50 acres (20 hectares)	1,600

Waste capacity value calculated assuming disposal cell depth of 65 feet (20 meters) and a 40 percent fill efficiency.

I.2.5 Preferred Alternative—Develop Zones 4 and 6 at TA–54

The Preferred Alternative is to develop both Zones 4 and 6, proceeding westward in a step-by-step fashion from the existing footprint of Area G. The majority of the area on top of Mesita del Buey (excluding the North Site) would effectively be designated for LLW management and disposal. The Preferred Alternative is shown in Figure I.2.5–1.

This alternative has been designated as preferred because it offers DOE several advantages. Because LLW disposal areas require long-term institutional control and LLW has been disposed of at both ends of Mesita del Buey (Area H and Area G, shown in Figure I.2.5–1), it would be more efficient to control the mesa top as one contiguous disposal area, continuing west from the existing Area G. Zones 4 and 6 on Mesita del Buey are not currently occupied or used by any T&E species. The space set aside might suffice for as long as 130 years. Setting aside an area that is more than adequate for the LLW disposal needs forecasted for 10 years gives DOE flexibility in case the needs have been underestimated. Finally, setting aside this entire area preserves DOE's flexibility to continue to dispose of LLW (north of the road in Zone 4) while addressing the issues of the archaeological sites in the remaining part of Zones 4 and 6.

Disposal cells would be excavated as needed. The development would ultimately be equivalent to the sum of that described individually for all of Zone 4 (section I.2.1.2)

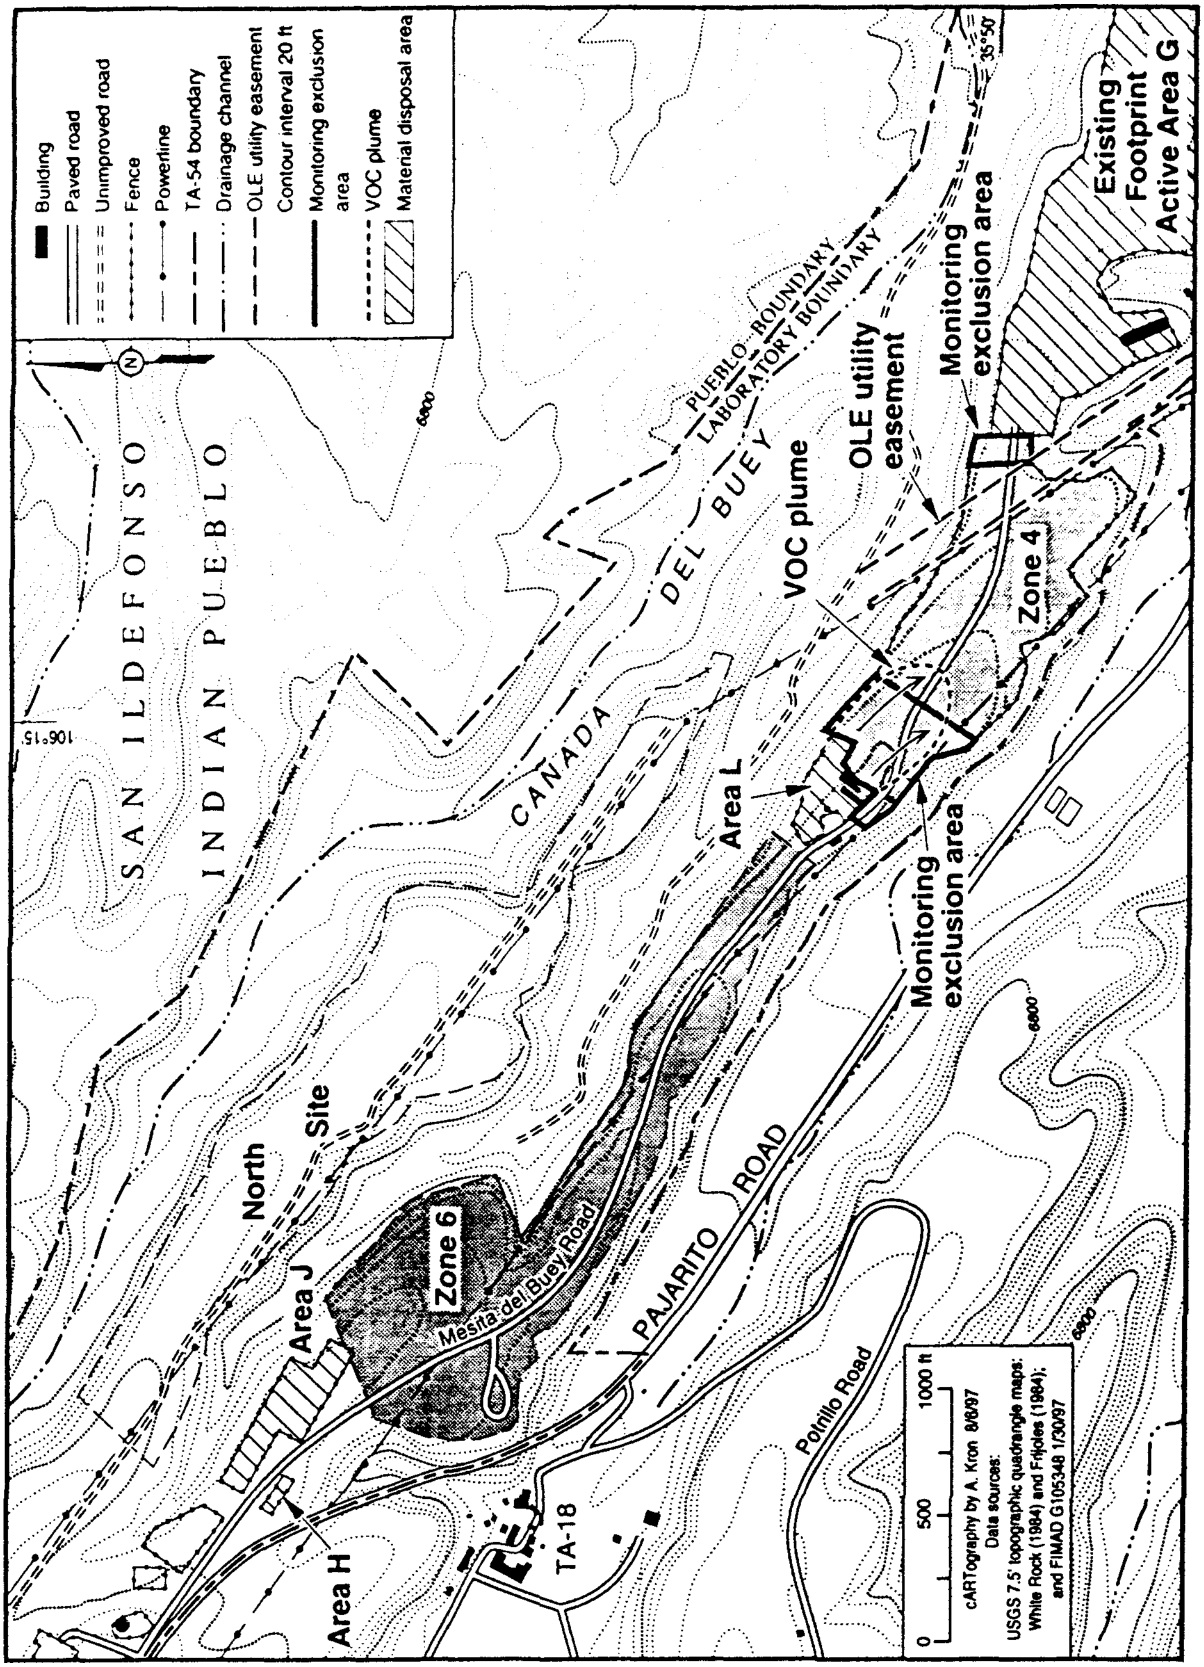

FIGURE I.2.5–1.—*Location of the Preferred Alternative Within TA–54.*

and Zone 6 (section I.2.2.2) added together, and as shown in Table I.2.5–1.

I.3 AFFECTED ENVIRONMENT

This section does not repeat information that is presented in volume I of the SWEIS; it focuses on alternative-specific information that is needed to illuminate the differences in alternatives. Table I.3–1 identifies the environmental resources common to this PSSC analysis and volume I of the SWEIS, along with their location in volume I and in this PSSC analysis. Table I.3–2 identifies environmental resources that are not discussed in this PSSC analysis, provides information about why they are not discussed further here, and identifies the locations of discussions in volume I of the SWEIS. Zones 4 and 6 and the North Site are on the top of the Mesita del Buey area at TA–54. The environmental conditions for the whole mesa top are described as a unit (as Mesita del Buey). TA–67, on Pajarito Mesa, is described separately.

I.3.1 Land Resources

Distances and directions from the residential areas, the San Ildefonso Pueblo boundary, and the Bandelier National Monument (BNM) boundary to the alternative locations are shown in Table I.3.1–1. The distances to these resources from existing Area G are included for comparison. Although the distances are shown to the nearest San Ildefonso Pueblo boundary, this is not the distance to a residential area at San Ildefonso. The mesa top on San Ildefonso Pueblo land nearest the DOE boundary may be used for other intermittent purposes, but no dwellings are located there. The nearest human habitations on pueblo land are at Totavi, some 3.6 miles (5.8 kilometers) northeast of Area G, and Otowi, which is farther away.

TABLE I.2.5–1.—*LLW Disposal Area Within the Preferred Alternative, Zones 4 and 6*

OPTION	APPROX. ACREAGE DISTURBED	APPROX. WASTE VOLUME (10^3 m^3)
Designate Zones 4 and 6 on Mesita del Buey, 70 acres (28 hectares)	41 acres (17 hectares)	1,350

Waste capacity value calculated assuming disposal cell depth of 65 feet (20 meters) and a 40 percent fill efficiency.
For Zone 4, option 2 (develop both north and south of the access road) is assumed.

I.3.1.1 *Land Use*

TA–54 is a designated waste management and disposal area and is not accessible to the general public. In contrast, TA–67 land is designated as an explosives test or storage area that is currently used as a safety buffer zone for nearby LANL explosives testing operations; LANL workers are excluded from TA–67 during tests.

I.3.1.2 *Visual Resources*

From Pajarito Road, motorists can see only the sides of support facilities and storage domes of the existing footprint of Area G on the edge of the mesa above, to the north of the road. The areas next to the structures at Area G are predominately grass-covered expanses (at closed disposal sites) surrounded by undeveloped areas that are forested with native shrubs and small trees. Mesita del Buey is not visible from the BNM Visitors' Center or developed campgrounds. It is visible from the nearest San Ildefonso Pueblo boundary, although not from the dwellings at Totavi and Otowi.

The easternmost end of TA–67 is visible from Pajarito Road but not from the BNM Visitors' Center, developed campgrounds, or San Ildefonso Pueblo land. The TA–67 area

TABLE I.3–2.—*Potential Environmental Resource Issues Addressed Only in Volume I of the SWEIS*

ENVIRONMENTAL RESOURCE	REASON NOT ADDRESSED IN THIS PSSC	LOCATION OF DISCUSSION
Parks, Forests, Conservation Areas, Areas of Recreational, Ecological, or Aesthetic Importance	Public access not permitted in any of the areas under consideration due to their present designated uses.	Volume I, section 4.1.1
Geology and Soils	Alternatives would involve the same types of surface soils and the same underlying Bandelier Tuff (Purtymun and Kennedy 1971, Nyhan et al. 1978, and Broxton and Chipera 1994).	Volume I, section 4.3
Water Resources	None of the alternatives would affect water resources. Any modifications to runoff patterns would be minor relocations. Surface water conditions are described in Reneau 1994, Banar 1996, and LANL 1996b.	Volume I, section 4.4
Wetlands	No wetlands present on mesa tops at TA–54 or TA–67 or in other locations that could be affected by any of the PSSC alternatives.	Volume I, section 4.5
Socioeconomics	The labor required to implement any of the alternatives is very small and well within the capacity of the local labor market.	Volume I, section 4.7

TABLE I.3.1–1.—*Distances to Residential Areas, Bandelier National Monument, and San Ildefonso Pueblo Boundaries from Each Alternative Location*

ALTERNATIVE LOCATION	FROM ROYAL CREST TRAILER PARK	FROM WHITE ROCK	FROM LOS ALAMOS TOWNSITE	FROM BANDELIER NATIONAL MONUMENT	FROM SAN ILDEFONSO PUEBLO BOUNDARY[a]
Zone 4	3.7 mi (5.9 km)	1.3 mi (2.1 km)	3.9 mi (6.2 km)	3.0 mi (4.8 km)	0.25 mi (0.4 km)
Zone 6	3.0 mi (4.8 km)	2.1 mi (3.4 km)	3.1 mi (5.0 km)	3.2 mi (5.1 km)	0.3 mi (0.5 km)
North Site, TA–54	2.9 mi (4.6 km)	2.1 mi (3.4 km)	3.0 mi (4.8 km)	3.2 mi (5.1 km)	0.05 mi (0.1 km)
TA–67	1.5 mi (2.4 km)	5.2 mi (8.3 km)	2.0 mi (3.2 km)	2.0 mi (3.2 km)	1.5 mi (2.4 km)
Area G Existing Footprint	1.6 mi (2.5 km)	1.0 mi (1.6 km)	4.2 mi (6.7 km)	3.2 mi (5.1 km)	0.13 mi (0.2 km)

[a] Distance to human habitation on the Pueblo lands at Totavi is 3.6 miles (mi) (5.8 kilometers [km]). Otowi is farther away.

presents a forested appearance with tall native trees.

I.3.1.3 *Noise*

Operations at TA–54 contribute to the overall background noise level generated by LANL activities primarily through the traffic into and away from the facilities located within the TA and from heavy machinery and equipment used to excavate the disposal cells and shafts and move waste containers. Actual operational noise heard outside of structures is mostly limited to the immediate vicinity of the activity; most of these noises are due to the routine movement of equipment and waste containers into and around the facilities. No measurements of environmental noise have been conducted within the TA–54 area; but the level of noise present there is fairly representative of other industrially developed sites around LANL.

TA–67 is undeveloped land covered with native vegetation. It is forested with native trees and contributes little to the overall background noise at LANL.

I.3.2 Air Quality

LANL maintains five meteorological towers around LANL, including one on Pajarito Road below the mesa-top location of TA–55 and Area G and one at TA–6 near TA–67 (LANL 1998b). These towers are instrumented to record temperature, relative humidity, wind direction, and wind velocity at 15-minute intervals. Statistics of wind measured 36 feet (11 meters) above ground level indicate that the prevailing daytime wind at TA–54 is from the southeast. At TA–6, the prevailing daytime wind is from the south.

On-site and off-site air monitoring stations collect samples from which the radionuclides in routine emissions and resuspended dust are analyzed. Eight such sampling stations are located around the developed footprint of Area G. LANL's annual surveillance reports document tritium, plutonium, uranium, and americium emissions in comparison with the DOE allowable concentration guides. These reports also contain a more thorough description of monitoring activities (LANL 1996b).

There are no monitoring stations in or bordering Zone 4, Zone 6, the North Site, or TA–67. Thus, there is no radioactive air quality information specific to any of the potential expansion areas.

The monitoring station nearest to these areas on Mesita del Buey, Station 36, is located at the west end of the developed footprint of Area G, just east of the monitoring exclusion area that separates the zone from the developed footprint of Area G (LANL 1996b). The air monitoring stations nearest to the TA–67 site are stations 76 and 78, approximately 5,000 feet (1.6 kilometers) to the east-southeast (LANL 1996b).

I.3.3 Ecological Resources

I.3.3.1 *Flora and Fauna*

Mesita del Buey

Most of Mesita del Buey, particularly Area G, is a high density area for LANL workers and traffic movement with continual disturbance related to waste disposal activities. The North Site is relatively undisturbed. The vegetation of the undisturbed portions of Mesita del Buey is primarily comprised of pinyon pine-juniper woodland with a ground cover of blue grama grass. In the disturbed areas, including the closed waste disposal cells, the vegetation is of mixed grasses and low-growing native plants (Usner 1996). The vegetation supports about 23 wildlife species that represent a broad diversity including insects, reptiles, amphibians, mammals, and birds. Some 95 species of birds, both resident and migratory varieties, have been identified in the general vicinity. Mule deer and elk are the most visible of the large mammals of the region. Other common species include black bear, mountain lion, bobcat, fox, and coyote. Small mammals known to inhabit the general area include species of voles, mice, and chipmunks (Banar 1996, Keller and Bennett 1996, Usner 1996).

TA–67

The TA–67 site is covered with the ponderosa pine habitat type, generally over the Pajarito Plateau's elevational ranges from 6,900 to 7,500 feet (2,100 to 2,300 meters). Overall, TA–67 is a fairly flat, wooded mesa top adjacent to moderately steep to very steep canyons; the north-facing canyon slope areas include fir and spruce species. The TA–67 area vegetation communities support about 90 wildlife species that represent a broad diversity, including insects, reptiles, amphibians, mammals, and birds.

Forty-nine species of birds, both resident and migratory varieties, have been identified in the general vicinity. Mule deer and elk are the most visible of the large mammals in the region. Other common species include black bear, mountain lion, fox, bobcat, and coyote (Cross and Usner 1996).

I.3.3.2 *Threatened and Endangered Species*

DOE analyzed existing available field information and used a preliminary model of nesting and roosting habitat for the Mexican spotted owl (*Strix occidentalis lucida*) to assess use of the TA–54 and TA–67 areas by species of animals and birds that are federally and state listed and protected as threatened or endangered. Three federally protected (also state listed) species of birds potentially use the surrounding area of TA–54 for habitat: the American peregrine falcon (*Falco peregrinus*), the Mexican spotted owl, and the southwestern willow flycatcher (*Empidonax traillii extimus*). However, species-specific field surveys located no T&E species habitat use for nesting or roosting purposes on Mesita del Buey itself, as well as none within 0.25 mile of the mesa top. The mesa top may provide some foraging habitat for the peregrine falcon. One federally protected species of bird, the Mexican spotted owl, potentially uses habitat in the TA–67 area for roosting and foraging purposes; potential nesting habitat is located next to TA–67 in the canyon area. No known use of this nesting habitat has occurred recently.

LANL conducted preliminary consultation with the U.S. Fish and Wildlife Service (FWS) concerning TA–67 development. According to the FWS, additional surveys would be needed in order to establish baseline information. Mitigation measures would be developed through consultations, in accordance with the *Endangered Species Act* (16 U.S.C. §1531), if the TA–67 alternative were to be implemented.

I.3.4 Human Health

I.3.4.1 *Radiological Dose*

Personnel at TA–54 are exposed to radiation from working with the various types of wastes managed there. Personnel are not exclusively assigned to one type of waste, so their doses represent an integration over all the jobs performed there. The LLW disposal cells are excavated by personnel who are part of the regular TA–54 workforce, so their doses cannot be partitioned to show only exposures received while excavating disposal cells. TRU and TRU mixed wastes (waste with both TRU and chemicals regulated as hazardous under the RCRA) produce the majority of the workers' doses. In 1995, of the 470 individuals working at Area G who wore dosimetry badges, 408 received no dose. In 1996, out of 228 badged personnel, 213 had no dose. The health effects of radiation are expressed as the increased risk or chance of dying from cancer at some point later in life (excess latent cancer fatality [LCF]). The average external doses of personnel assigned to TA–54 who wear dosimetry badges and received detectable (non-zero) doses in 1995 and 1996 with associated health effects are shown in Table I.3.4.1–1. Dose and health effect information on LANL personnel working in other locations under the Expanded Operations Alternative is presented in volume I of the SWEIS, chapter 5, section 5.3.6. (Long-term public health impacts from disposal operations are discussed in section 5.3.3.5 of volume I and the Area G Performance Assessment [LANL 1998f]).

Area development and disposal cell construction activities would not be expected to expose equipment operators to radioactive material, regardless of alternative location. Thus, there would be no worker dose associated with area development and cell construction. Any workers who are on the site for a short time to construct disposal cells and support facilities and do not work in the vicinity of TRU wastes should receive no work-related dose, regardless of alternative location.

TABLE I.3.4.1–1.—*Annual Individual Worker Dose (External Dose) and Health Effects at Area G (1995, 1996)*

TOTAL BADGED WORKERS AT AREA G	INDIVIDUALS WITH ZERO DOSE	AVERAGE DOSE FOR INDIVIDUALS WITH MEASURABLE DOSE	HEALTH EFFECT—CHANCE OF EXCESS LCF IN THE EXPOSED POPULATION
470 Individuals in 1995	408 (87 percent)	18 millirem (62 individuals)	less than 1—(0.00045 or 4 in 10 thousand)
228 Individuals in 1996	213 (93 percent)	38 millirem (15 individuals)	less than 1—(0.00023 or 2 in 10 thousand)
DOE Individual Annual Occupational Dose Limit	—	5,000 millirem[a] (5 rem)	less than 1—(0.0020 or 20 in 10 thousand)

[a] DOE 1994

I.3.4.2 *Construction Activities*

The regular workforce at Area G excavates new disposal cells as part of normal operations. Construction and relocation activities can expose workers to a variety of risks, such as being crushed beneath heavy equipment, back injuries, electrical hazards, and those related to working below grade. All work is performed according to facility procedures for each type of task and LANL-wide general standards. Worker health is protected by following administrative controls and wearing personal protective equipment such as hard hats and steel-toed boots, as needed. Information on safety and construction-related accidents that have occurred at LANL is found in chapter 4 of volume I.

I.3.5 Environmental Justice

The WM PEIS has identified a potential environmental justice issue because of the proximity of LLW disposal areas at LANL to minority and low-income populations, such as the Native Americans at San Ildefonso Pueblo and the Hispanic population in Española, Santa Fe, and the surrounding area (DOE 1997). As noted in section I.1.1, the northern boundary of LANL at TA–54 is San Ildefonso Pueblo land. However, the nearest human habitations on San Ildefonso Pueblo land are at Totavi, some 3.6 miles (5.8 kilometers) from Area G, and at Otowi, which is farther away. Distance is even farther to Española, the nearest town with a predominately Hispanic population. The distances to the residential areas from each of the proposed LLW disposal locations are presented in Table I.3.1–1. The environmental justice affected environment is discussed further in chapter 4, section 4.8, of volume I.

I.3.6 Cultural Resources

The presence of TCPs in the Mesita del Buey area and the TA–67 area is unknown. Cultural resource surveys have been conducted over most of TA–54 and over a portion of TA–67 to identify archeological sites within those areas.

Cultural resource surveys conducted over Mesita del Buey within the designated footprint of Area G have identified 20 archaeological sites in the area west and north of the existing Area G disposal area. Sixteen of these 20 sites have been evaluated for inclusion on the NRHP. Of the 16 sites evaluated for register inclusion, 8 are located in Zone 4 to the south of the roadway, and 1 is located to the north of the roadway in an ER monitoring zone. All 9 sites within Zone 4 are Coalition Period pueblo roomblocks (A.D. 1100 through A.D. 1325). An archeological data recovery plan on seven of the sites located south of the road in Zone 4 that are eligible for inclusion on the NRHP (Larson 1991b) has been approved by the New Mexico SHPO, and site work to implement the recovery plan has been initiated but not completed; the remaining site on the south side of the road is not eligible for NRHP inclusion. The single site located north of the roadway in Zone 4 is not included in the data recovery plan because there are no current plans to excavate this site since it is located within an ER monitoring zone. Seven of the 16 archaeological sites evaluated for NRHP inclusion were identified within the Zone 6 area of Mesita del Buey. All of these seven sites are pueblo roomblocks dating from the Coalition Period and the Classic Period (A.D. 1325 through A.D. 1600) (Larson 1997). Consultation with the SHPO and the four Accord Pueblos has not yet been initiated by DOE for these seven sites. The remaining 4 sites of the total of 20 sites located to the west and north of the existing Area G disposal area are not believed to be eligible for inclusion on the NRHP. Surveys of these sites were not comprehensive, however, and a rigorous survey and additional consultation with the SHPO and Accord Pueblos, together with site work to implement such a plan, have not yet been undertaken by DOE.

Cultural resource surveys of the TA–67 area of interest revealed the presence of 11 archaeological sites and these have been evaluated for eligibility for inclusion on the NRHP. These sites are from the Coalition and Classic Periods (LANL 1998c). Of the 11 sites, all but 1 are eligible for inclusion in the register. An archaeological data recovery plan on the 10 sites, together with consultation with the SHPO and Accord Pueblos, and site work to implement such a plan have not yet been undertaken by DOE.

I.3.7 Waste Management (Construction Refuse)

Uncontaminated wastes produced by operations at LANL, such as construction debris and office refuse, are collected by a subcontractor and recycled where feasible. The remaining uncontaminated wastes are disposed of in the Los Alamos County Landfill.

I.3.8 Environmental Restoration

I.3.8.1 *Mesita del Buey*

All of TA–54 has been placed in ER Operable Unit 1148. Eventual cleanup and site closure would follow ER procedures and other applicable regulations in place at that time.

Area L was historically used as a disposal site for hazardous chemical wastes and has a VOC vapor plume in its subsurface. Various chemicals are present in the plume; the one in highest concentration is TCE. Constituents and concentrations of the VOC plume are listed in appendix I.B. This plume extends about 55 feet (20 meters) east of Area L into Zone 4. Within Zone 4, there are two ER monitoring zones, as shown in Figure I.1.1.1–1. The first is located immediately east of Area L and covers about 4 acres (1.6 hectares). The second comprises about 1 acre (0.4 hectare) immediately west of the current disposal area at Area G. Monitor wells in both monitoring exclusion zones are being tested on a quarterly basis to determine movement of pore gas in the vadose zone. The plume has not expanded spatially in the last 5 years. There are no known areas of contamination in Zone 6 or the North Site.

I.3.8.2 *TA–67*

Because TA–67 is in the blast circles for active firing sites, it is possible that debris and airborne particulates from test activities have been deposited onto portions of TA–67. To date, no such debris or contamination has been identified at this site. In addition, TA–67 is not currently an ER operable unit area.

I.3.9 Traffic

Traffic to and from Los Alamos County and within LANL is discussed in volume I, chapter 4, section 4.10. At present, LLW is moved to Area G by truck. Construction materials are also moved to LANL and within LANL by truck. Access to Mesita del Buey is via Pajarito Road (State Route 4). Access to TA–67 is via West Jemez Road (State Route 501).

I.3.10 Comparison of Environmental Conditions at Alternative Locations

The environmental conditions at each of the identified alternative locations are summarized and compared in Table I.3.10–1.

The conditions for the Preferred Alternative are the sum of the individual conditions for Zones 4 and 6, except for distances and noise.

I.4 ENVIRONMENTAL CONSEQUENCES

The environmental consequences of developing new LLW disposal areas at LANL are presented

TABLE I.3.10–1.—*Comparison of Environmental Resource Conditions in Alternative Locations for Low-Level Radioactive Waste Disposal*

	PREFERRED ALTERNATIVE			
ENVIRONMENTAL RESOURCE CONDITION	**ZONE 4 (AREA G, TA–54)**	**ZONE 6 (TA–54)**	**NORTH SITE (TA–54)**	**TA–67**

[a] Distance from the existing LLW disposal site in Area G to the San Ildefonso Pueblo boundary is 0.13 mi (0.2 km).
dBA = decibels A-weighted frequency scale

for each alternative and compared below. The differences among alternatives derive from development and construction activities at the different locations where LLW would be disposed. The primary differences among alternatives relate to current land use and surface features. All alternatives call for constructing and developing an LLW disposal area by excavating into the same underlying Bandelier Tuff. The disposal volume to be excavated and the consequences of excavating the tuff itself are assumed to be equivalent for all alternatives. The impacts of LLW management and disposal operations including post-closure are addressed in chapter 5 of volume I. The following siting, development, and construction impacts would be in addition to the operational impacts for LLW management, including disposal.

I.4.1 Develop Zone 4 at TA–54

I.4.1.1 *Land Resources*

Land Use

Because Area G (80 acres [32 hectares]) has been dedicated for LLW disposal, developing Zone 4 would represent no change in land use (DOE 1979). Land use for the entire TA–54 area has been designated for research and development and waste disposal (volume I, chapter 4, Figure 4.1.1.2–1).

Visual Resources

New disposal cells would not be visible from Pajarito Road. New disposal cells would be visible from the boundary of the San Ildefonso Pueblo, but not from the human habitations at White Rock, Los Alamos, Totavi, Otowi, or BNM.

Noise

Excavating new LLW disposal cells would produce the same noise at the point of excavation for all alternatives because the same type of tuff underlies all locations. As shown in Table I.4.1.1–1, cell construction in Zone 4 would be audible at the San Ildefonso Pueblo boundary, but not at the human habitations at Totavi and Otowi, which are much farther away than White Rock and the Los Alamos townsite. Disposal cell construction could be audible above background levels at the nearest point in White Rock. Noise levels at residential areas due to the excavation and construction activities could be audible but within normal levels in the

TABLE I.4.1.1–1.—*Sound Level Estimates[a] from Excavations/Construction in Zone 4 at Receptor Locations[b]*

ALTERNATIVE	(OPERATORS) 3 to 6 ft (1 to 2 m) DISTANCE, dBA	ON-SITE PERSONNEL, 50 ft (15 m) DISTANCE, dBA	WHITE ROCK, dBA	ROYAL CREST TRAILER PARK, dBA	LOS ALAMOS TOWNSITE, dBA	BANDELIER NATIONAL MONUMENT, dBA	SAN ILDEFONSO PUEBLO BOUNDARY, dBA
Zone 4 Disposal Cell Excavation	90 to 113[c]	72 to 95	30 to 53	20 to 43	17 to 40	22 to 45	45 to 68
Normal Background	NA	NA	38 to 51	no data (assume 38 to 51)	38 to 51	31 to 35	no data (assume 31 to 35)

[a] Values calculated from standard noise ranges at 50 feet (ft) (15 meters [m]) using the inverse square relationship: sound $level_1$ - sound $level_2 = 20 \log r_2 r_1^{-1}$ where 1 and 2 represent two locations.
[b] Distances from residential areas shown in Table I.3.1–1.
[c] Standard construction equipment noise ranges (from Canter 1996).
NA = Not applicable

Los Alamos townsite and at Royal Crest Trailer Park. Noise from cell construction could also be audible above background at the roadway boundary to BNM, but not at the Visitors' Center or in the developed campgrounds. The estimates presented are very conservative; in practice, the uneven terrain, intervening vegetation, and direction of air movement would further reduce the noise at receptor locations.

The sound levels at and near the excavation equipment are sufficiently high that operators would be provided with hearing protection. Hearing protection may be provided for other personnel in the vicinity of construction, as needed.

I.4.1.2 *Air Quality*

As LLW disposal cells are excavated, dust particles and vehicle exhaust fumes would be generated by bulldozers, back hoes, and similar construction equipment. LANL personnel would use standard dust suppression methods such as minimizing the area of ground disturbed and misting (LANL 1996c). Excavating disposal cells would not be expected to degrade the quality of air in residential areas.

If the VOC plume has spread from Area L into Zone 4 and the soil and tuff in that location are excavated, VOC components could be released into the air. Consequences to air quality have not been estimated, pending the outcome of the study on risk related to this VOC plume.

Part or all of the wood from trees cleared from Zone 4 would be chipped and burned or used as mulch on the site. Burning would be conducted, under an open burning permit obtained from the New Mexico Environment Department (NMED), such that the air quality standards would not be violated.

I.4.1.3 *Ecological Resources*

Flora and Fauna

Developing Zone 4 would require that most or all of the pinyon-juniper tree cover on 24 acres (10 hectares) be removed. The vegetative coverage of Zone 4 is comparable in density to the general forested area along the mesa top. The wood would be chipped and burned or used for mulch on the site. This would change or eliminate part of the habitat of birds and small mammals living in or around Zone 4. The habitat change would be small (24 acres [10 hectares]) compared to the available habitat remaining in the area (which is many hundreds of acres in size). Construction noise and activity would cause minor and short-term disturbance to wildlife utilizing adjacent habitat during the various development phases. Because the new cells would be within an area that is already fenced, no new impacts are anticipated to the large game animals that utilize the area.

Threatened and Endangered Species

A peregrine falcon nest site is located more than 3 miles (4.8 kilometers) from the proposed expansion areas at TA–54. Peregrine falcons have a wide foraging area, typically up to 12.3 miles (19.8 kilometers) from their nest. The total amount of foraging habitat for this nesting location is 126,805 acres (50,722 hectares), not including developed areas. Developing Zone 4 would require that trees be removed and result in a loss of about 24 acres (10 hectares) of possible foraging habitat (approximately 0.03 percent of available forage area) (Keller and Bennett 1996). The removal of less than 1 percent of available forage area would not result in an appreciable effect on this species.

I.4.1.4 *Environmental Justice*

Developing an LLW disposal area at any location on Mesita del Buey would place the development and subsequent operations adjacent to the San Ildefonso Pueblo boundary but not to the nearest human habitations on pueblo land, as shown in Table I.3.1–1. The development would be visible from the pueblo boundary, and the noise from disposal cell excavations would be audible, should anyone be present at the boundary. However, the noise is not in the range considered harmful to human health.

I.4.1.5 *Cultural Resources*

DOE lacks information regarding the presence of TCPs within TA–54. In the absence of specific information, the consequences of developing Zone 4 on such resources can only be estimated in a qualitative manner. If these resources are present in the Zone 4 area, they would either be destroyed by construction or diminished in value by alteration of the area. If none of these resources are present, no effect would be expected.

If only the area within Zone 4 on the north side of the road were developed and the monitoring exclusion zone were avoided, no archaeological sites would be disturbed. Eight archaeological sites within Zone 4 could be affected or destroyed by constructing an LLW disposal facility that includes the south side of Mesita del Buey Road. All of the eight sites are eligible for the NRHP (Larson 1991a). Two of the eligible sites have already been partially tested or excavated in accordance with a 1991 data recovery plan (Larson 1991b and Larson 1997). If the area on the south side of the road were to be developed, all of the sites would have to be excavated prior to the start of project activities. DOE would need to consult with the four Accord Pueblos and take their comments into consideration in the data recovery plan before the archaeological excavations at Zone 4 could be continued.

I.4.1.6 *Waste Management (Construction Refuse)*

Waste from disposal cell construction (i.e., rock and soil) would be managed at the location (used for fill and for cover or disposed of). No other construction would be needed.

I.4.1.7 *Environmental Restoration*

All of TA–54 is considered a part of ER Operable Unit 1148. If Zone 4 were to be developed, consideration would have to be given to the VOC plume originating in Area L. Possible effects of excavating cells in Zone 4 on the VOC plume and the contaminant source at Area L are not known at present. LANL personnel have initiated a study of the risks posed by the old waste disposal at Area L and the VOC plume, but there is no information at present.

I.4.1.8 *Traffic*

As noted in section I.2.1.2, no new construction (except for excavation of disposal cells) would be required to implement this alternative. Thus, developing Zone 4 would not require construction materials to be transported to the site nor generate construction wastes to be removed from the site. Developing Zone 4 would have no effect on the flow of traffic on public roads.

I.4.2 Develop Zone 6 at TA–54

I.4.2.1 *Land Resources*

Land Use

Because the whole of Mesita del Buey, including Area G, has been identified for management of solid wastes, developing Zone 6 would not represent a change in land use category (DOE 1979).

Visual Resources

New disposal cells would not be visible from Pajarito Road. New cells would be visible from the boundary of the San Ildefonso Pueblo, but not from the human habitations at White Rock, Los Alamos, Totavi, Otowi, or BNM.

Noise

The noise level to which people could be exposed varies with receptor location, as shown in Table I.4.2.1–1. Disposal cell construction in Zone 6 would be audible at the San Ildefonso Pueblo boundary but not at the human habitations at Totavi and Otowi, which are much farther away than White Rock and the Los Alamos townsite. Noise levels at residential areas due to the excavation and construction activities would be audible, but within normal levels in White Rock, the Los Alamos townsite, and at the Royal Crest Trailer Park. Noise from disposal cell construction could be audible above background at the roadway boundary to BNM, but not at the Visitors' Center nor in the developed campgrounds. The estimates presented are very conservative; in practice, the uneven terrain, intervening vegetation, and direction of air movement would further reduce the noise at receptor locations.

The sound levels at and near the excavation equipment are sufficiently high that operators would be provided with hearing protection. Hearing protection may be provided for other personnel in the vicinity of construction, as needed.

I.4.2.2 *Air Quality*

As discussed in section I.4.1.2, LANL personnel would use standard dust suppression methods. Excavating disposal cells would not be expected to degrade the quality of air in residential areas.

The wood from trees cleared from Zone 6 would be chipped and burned or used as mulch on the site. Burning would be conducted under an open burning permit obtained from NMED, such that the air quality standards would not be violated.

I.4.2.3 *Ecological Resources*

Flora and Fauna

Developing Zone 6 would require that most or all of the pinyon-juniper tree cover on 17 acres (7 hectares) be removed. The vegetative

TABLE I.4.2.1–1.—*Sound Level Estimates[a] from Excavations/Construction in Zone 6 at Receptor Locations[b]*

ALTERNATIVE	OPERATORS, 3 to 6 ft (1 to 2 m) DISTANCE, dBA	ON-SITE PERSONNEL, 50 ft (15 m) DISTANCE, dBA	WHITE ROCK, dBA	ROYAL CREST TRAILER PARK, dBA	LOS ALAMOS TOWNSITE, dBA	BANDELIER NATIONAL MONUMENT, dBA	SAN ILDEFONSO PUEBLO BOUNDARY, dBA
Zone 6 Disposal Cell Excavation	90 to 113[c]	72 to 95	24 to 47	22 to 45	22 to 45	22 to 45	42 to 65
Normal Background	NA	NA	38 to 51	no data (assume 38 to 51)	38 to 51	31 to 35	no data (assume 31 to 35)

[a] Values calculated from standard noise ranges at 50 ft (15 m), using the inverse square relationship: sound $level_1$ - sound $level_2 = 20 \log r_2 r_1^{-1}$ where 1 and 2 represent two locations.
[b] Distances from residential areas shown in Table I.3.1–1.
[c] Standard construction equipment noise ranges (from Canter 1996).
NA = Not applicable

coverage of Zone 6 is comparable in density to the general forested area along the mesa top. The wood would be chipped and burned or used for mulch on the site. This would change or eliminate part of the habitat for birds and small mammals living in and around Zone 6. The habitat change would be small (17 acres [7 hectares]) compared to the available habitat remaining in the area (which is many hundreds of acres in size). Construction noise and activity would cause minor and short-term disturbance to wildlife utilizing adjacent habitat during the various development phases. Because the new disposal cells and shafts would only be fenced during the time that they are active, and the whole area would not be fenced, no new impacts are anticipated to the large game animals that utilize the area.

Threatened and Endangered Species

A peregrine falcon nest site is located more than 3 miles (4.8 kilometers) from both proposed expansion areas at TA–54. Peregrine falcons have a wide foraging area, typically up to 12.3 miles (19.8 kilometers) from their nest. The total amount of foraging habitat for this nesting location is 126,805 acres (51,318 hectares), not including developed areas. Cutting the trees would remove some 17 acres (7 hectares, less than 0.02 percent) of possible foraging habitat for peregrine falcons, in the event that this alternative is chosen (Keller and Bennett 1996). The removal of less than 1 percent of available foraging habitat area would not result in an appreciable effect on this species.

I.4.2.4 *Environmental Justice*

The disposal area development would be visible from the pueblo boundary, and the noise from disposal cell excavations would be audible, should anyone be present at the boundary. However, the noise is not in the range considered harmful to human health.

I.4.2.5 *Cultural Resources*

DOE lacks information regarding the presence of TCPs within TA–54. In the absence of such information, the potential consequences of developing Zone 6 can only be estimated qualitatively. If these resources are present in Zone 6, they would either be destroyed by construction or diminished in value by alteration of the area. If no such resources are present, no effect would be expected.

Seven archaeological sites would be affected or destroyed by constructing an LLW disposal facility at Zone 6. The cultural resource report documenting the survey has not been submitted to the SHPO, and official eligibility determinations for the seven sites have not been made. In compliance with current regulations, adverse effects to the NRHP eligible sites could be successfully mitigated by conducting archaeological excavations designed to recover scientific data. If Zone 6 is selected as the location for an LLW facility, DOE would prepare a proposal for mitigation of adverse effects to the eligible sites (a data recovery plan) and incorporate the concerns of the Accord Pueblos. The New Mexico SHPO would review the document prior to implementation of mitigation measures and be requested to concur in a determination of no adverse effect before the start of project activities.

I.4.2.6 *Waste Management (Construction Refuse)*

Waste from disposal cell construction (i.e., rock and soil) would be managed at the location (used for fill and for cover or disposed of). No other construction would be needed.

I.4.2.7 *Environmental Restoration*

All of TA–54 is considered part of ER Operable Unit 1148. There would be no additional ER implications from disposing of LLW in Zone 6.

I.4.2.8 *Traffic*

As noted in section I.2.2.2, the only construction required to implement this alternative would be to fence cells being excavated and filled. Thus, developing Zone 6 would not require construction materials to be transported to the site nor generate construction wastes to be removed from the site. Developing Zone 6 would have no effect on the flow of traffic on public roads.

I.4.3 Develop the North Site at TA–54

I.4.3.1 *Land Resources*

Land Use

Because the whole of Mesita del Buey, including Area G, has been identified for management of solid wastes, developing the North Site would not represent a change in land use category (DOE 1979).

Visual Resources

New disposal cells would not be visible from Pajarito Road. New cells would be visible from the boundary of the San Ildefonso Pueblo, but not from the human habitations at White Rock, Los Alamos, Totavi, Otowi, or BNM.

Noise

The noise level to which people could be exposed varies with receptor location, as shown in Table I.4.3.1–1. Disposal cell construction at the North Site would be audible at the San Ildefonso Pueblo boundary, but not at the human habitations at Totavi and Otowi, which are much farther away than White Rock and the Los Alamos townsite. Noise levels at residential areas due to the excavation and construction activities would be audible but within normal levels in White Rock, the Los Alamos townsite, and at the Royal Crest Trailer Park. Noise from cell construction could be audible above background at the roadway boundary to BNM, but not at the Visitors' Center nor in the developed campgrounds. The estimates presented are very conservative; in practice, the uneven terrain, intervening vegetation, and direction of air movement

TABLE I.4.3.1–1.—*Sound Level Estimates[a] from Excavations/Construction in the North Site at Receptor Locations[b]*

ALTERNATIVE	OPERATORS, 3 to 6 ft (1 to 2 m) DISTANCE, dBA	ON-SITE PERSONNEL, 50 ft (15 m) DISTANCE, dBA	WHITE ROCK, dBA	ROYAL CREST TRAILER PARK, dBA	LOS ALAMOS TOWNSITE, dBA	BANDELIER NATIONAL MONUMENT, dBA	SAN ILDEFONSO PUEBLO BOUNDARY, dBA
North Site	90 to 113[c]	72 to 95	24 to 47	22 to 45	22 to 45	22 to 45	54 to 79
Normal Background	NA	NA	38 to 51	no data (assume 38 to 51)[d]	38 to 51	31 to 35	no data (assume 31 to 35)[d]

[a] Values calculated from standard noise ranges at 50 ft (15 m), using the inverse square relationship: sound level$_1$ - sound level $_2$ = 20 log r_2 r_1^{-1} where 1 and 2 represent two locations.
[b] Distances from residential areas shown in Table I.3.1–1.
[c] Standard construction equipment noise ranges (from Canter 1996).
[d] In these cases, noise levels were assumed to be the same as those measured in nearby locations. The noise level at the Royal Crest Trailer Park was assumed to be the same as that measured at the Los Alamos townsite, and the noise level at the San Illdefonso boundary is assumed to be the same as that at the adjacent BNM land (refer to Figure I.1.1–1).
NA = Not applicable

would further reduce the noise at receptor locations.

The sound levels at and near the excavation equipment are sufficiently high that operators would be provided with hearing protection. Hearing protection may be provided for other personnel in the vicinity of construction, as needed.

I.4.3.2 *Air Quality*

As discussed in section I.4.1.2, LANL personnel would use standard dust suppression methods. Excavating cells would not be expected to degrade the quality of air in residential areas.

Part or all of the wood from trees cleared from the North Site would be chipped and burned or used as mulch on the site. The burning would be conducted under an open burning permit obtained from NMED, such that the air quality standards would not be violated.

I.4.3.3 *Ecological Resources*

Flora and Fauna

Developing the North Site could also require that the pinyon-juniper tree cover on 49 acres (20 hectares) be removed. The vegetative coverage of the North Site is comparable to the general forested area along the mesa top. The wood would be chipped and burned or used for mulch on the site. This would change or eliminate part of the habitat for birds and small mammals living in or around the North Site. The habitat change would be small, compared to the available 49 acres (20 hectares) of habitat remaining in the area, which is many hundreds of acres in size. Construction noise and activity would cause minor and short-term disturbance to wildlife utilizing adjacent habitat during the various development phases. Because the new disposal cells and shafts would only be fenced during the time that they are active, and the whole area would not be fenced, no new impacts are anticipated to the large game animals that utilize the area.

Threatened and Endangered Species

Peregrine falcons have a wide foraging area, typically up to 12.3 miles (19.8 kilometers) from their nest, which is more than 3 miles (5 kilometers) away from the North Site. The total amount of forage habitat for this nesting location is 126,805 acres (50,722 hectares), not including developed areas. At the North Site, the loss of foraging habitat due to removing trees would be 40 acres (16 hectares), approximately 0.05 percent (Keller and Bennett 1996). The removal of less than 1 percent of available foraging habitat area would not result in an appreciable effect on this species.

I.4.3.4 *Environmental Justice*

The development would be visible from the pueblo boundary, and the noise from disposal cell excavations would be audible, should anyone be present at the boundary. However, the noise is not in the range considered harmful to human health.

I.4.3.5 *Cultural Resources*

Cultural resource surveys of the North Site identified four archaeological sites. The surveys were not comprehensive; a rigorous survey would be needed if this alternative were selected, and additional sites may be identified. As discussed in section I.4.2.5, if this alternative were selected, a cultural resource report would be submitted to the SHPO and Accord Pueblos, and their comments would be taken into consideration in developing a data recovery plan.

DOE lacks information regarding the presence of TCPs within TA–54. In the absence of such information, the potential consequences of developing the North Site can only be estimated qualitatively. If these resources are present within the North Site area, they would either be destroyed by construction or diminished in value by the alteration of the area. If none of these resources are present, then no effect would be expected.

I.4.3.6 *Waste Management (Construction Refuse)*

Waste from disposal cell construction (i.e., soil and rock) would be managed at the location (used for fill and for cover or disposed of). Any refuse from utility line construction would be disposed of in the Los Alamos County Landfill. The amount of refuse would be very small.

I.4.3.7 *Environmental Restoration*

All of TA–54 is considered a part of ER Operable Unit 1148. There would be no additional ER implications from disposing of LLW in the North Site.

I.4.3.8 *Traffic*

As noted in section I.2.3.2, the only construction required to implement this alternative would be to pave the unpaved road down the mesa top and install utility lines and a decontamination facility (wash pad for a truck). Fencing would be needed for disposal cells being excavated and filled. Developing the North Site would require perhaps a dozen truckloads of construction materials to be transported to the site. No construction wastes would be removed from the site. Developing the North Site would have no noticeable effect on the flow of traffic on public roads.

I.4.4 Develop a New Disposal Site at Another LANL Technical Area (TA–67)

I.4.4.1 *Land Resources*

Land Use

Currently, TA–67 is a secured area used as an inactive buffer zone for HE research and development. It is within the blast circles for active HE firing sites at TA–15 and TA–40. Its development for LLW disposal would require dual land use designation. Development of an LLW disposal site within TA–67 would require that disposal operations be suspended temporarily during HE open firing tests. It would result in a change in land use designation from Explosives Use to Explosives/Waste Disposal.

The possible presence of a geologic fault underlying the western edge of TA–67 could potentially disqualify this site from further consideration as a disposal area. Should development be pursued in the future, additional investigation would be required.

Visual Resources

New disposal cells would not be visible from Pajarito Road. If the TA–67 site was developed, the support structures would probably be visible from Pajarito Road and possibly from State Road 4 bordering BNM, but not from the San Ildefonso Pueblo land. If a bridge were constructed over Threemile Canyon, this might also be visible from Pajarito Road. None of these would be visible from the boundary of the San Ildefonso Pueblo, nor from the human habitations at White Rock, Los Alamos, Totavi, Otowi, or BNM.

Noise

If TA–67 were developed, the additional construction would cause noise generation intermittently for 1 to 2 years, in addition to the disposal cell excavation noise. Trenching for utility lines with a back hoe would produce the loudest of these operational noises. The noise level for back hoe operations (72 to 92 decibels A-weighted frequency scale [dBA]) is bounded by that for tractor operations (76 to 95 dBA) (Canter 1996).

The noise level to which people could be exposed varies with receptor location, as shown in Table I.4.4.1–1. Disposal cell construction at TA–67 could be audible above background level in White Rock, the Los Alamos townsite, and at the Royal Crest Trailer Park. Noise from cell construction could be audible above background at the roadway boundary to BNM, but not at the Visitors' Center nor in the developed campgrounds. The estimates presented are very conservative; in practice, the uneven terrain, intervening vegetation, and direction of air movement would further reduce the noise at receptor locations.

The sound levels at and near the excavation equipment are sufficiently high that operators would be provided with hearing protection. Hearing protection may be provided for other personnel in the vicinity of construction, as needed.

I.4.4.2 *Air Quality*

As discussed in section I.4.1.2, LANL personnel would use standard dust suppression methods. Excavating cells would not be expected to degrade the quality of air in residential areas.

Considerable additional construction would be required to develop the TA–67 site. These activities would also generate more dust particles and vehicle exhaust fumes. The consequences to air quality have not been estimated but would be comparable to other ground-breaking activities (less than highway construction) and of short duration.

Part or all of the wood from trees cleared from TA–67 would be chipped and burned or used as mulch on the site. The burning would be conducted under an open burning permit obtained from NMED, such that the air quality standards would not be violated.

TABLE I.4.4.1–1.—*Sound Level Estimates[a] from Excavations/Construction in TA–67 at Receptor Locations[b]*

ALTERNATIVE	OPERATORS, 3 to 6 ft (1 to 2 m) DISTANCE, dBA	ON-SITE PERSONNEL, 50 ft (15 m) DISTANCE, dBA	WHITE ROCK, dBA	ROYAL CREST TRAILER PARK, dBA	LOS ALAMOS TOWNSITE, dBA	BANDELIER NATIONAL MONUMENT dBA	SAN ILDEFONSO PUEBLO BOUNDARY, dBA
TA–67	90 to 113[c]	72 to 95	18 to 41	28 to 51	27 to 40	27 to 40	27 to 50
Normal Background	NA	NA	38 to 51	no data (assume 38 to 51)[d]	38 to 51	31 to 35	no data (assume 31 to 35)[d]

[a] Values calculated from standard noise ranges at 50 ft (15 m), using the inverse square relationship: sound $level_1$ - sound level $_2$ = 20 log r_2 r_1^{-1} where 1 and 2 represent two locations.
[b] Distances from residential areas shown in Table I.3.1–1.
[c] Standard construction equipment noise ranges (from Canter 1996).
[d] In these cases, noise levels were assumed to be the same as those measured in nearby locations. The noise level at the Royal Crest Trailer Park was assumed to be the same as that measured at the Los Alamos townsite, and the noise level at the San Illdefonso boundary is assumed to be the same as that at the adjacent BNM land (refer to Figure I.1.1–1).
NA = Not applicable

I.4.4.3 *Ecological Resources*

Flora and Fauna

Developing TA–67 could require that most or all of the ponderosa pine, pinyon, and juniper tree cover on 60 acres (24 hectares) be removed. The vegetative coverage of mostly mature trees over 40 feet (12 meters) tall is comparable in density to the general forested area along the mesa top. This wood would be chipped and burned or used as mulch on the site.

This development would change or eliminate part of the habitat for birds and small mammals living in and around the developed part of TA–67. The habitat change would be small because the disturbed area would be about 60 acres (24 hectares) within a more than 1,000-acre (greater than 400-hectares) relatively undisturbed area. Construction noise and activity would cause minor and short-term disturbance to wildlife utilizing adjacent habitat during the various development phases. Because the new disposal cells would only be fenced during the time that they are active, and the whole area would not be fenced, no new impacts are anticipated to the large game animals that utilize the area.

Threatened and Endangered Species

The Mexican spotted owl has been found to nest over 1 mile (1.6 kilometers) away from TA–67 within the general vicinity of the southern portion of TA–15; however, potential nesting habitat is present near TA–67 within 0.25 mile (0.4 kilometer) of the proposed disposal site. The TA–67 location is also within potential roosting and foraging habitat areas. Removing ponderosa pine trees at the site would decrease the potential foraging habitat for the Mexican spotted owl by about 1.3 percent and the potential roost-only habitat by about an equal amount (Keller and Bennett 1996). Potential nesting habitat may be adversely affected in that noise and light from the disposal site could reduce the desirability of the area and its future usefulness to the species.

I.4.4.4 *Environmental Justice*

The disposal area development would not be visible from the pueblo boundary, and the noise from disposal cell excavations would not be audible, should anyone be present at the boundary.

I.4.4.5 *Cultural Resources*

Eleven specific archaeological sites would be affected or destroyed by the construction of an LLW disposal facility at TA–67. In addition to these 11 sites, people working in the area may be able to reach and disturb other sites in close proximity to the construction area. One site has been determined not to be eligible for the NRHP. Adverse effects to the 10 NRHP-eligible sites could be mitigated by conducting archaeological excavations designed to recover scientific data. A survey report documenting the results of the 1992 to 1993 archaeological survey would be sent to the SHPO in order to begin the required consultation process. The procedure would be as described in section I.4.2.5 for Zone 6.

DOE lacks information regarding the presence of TCPs within TA–67. In the absence of specific information on such resources, the potential consequences of developing the TA–67 site on such resources can only be estimated qualitatively. If these resources are present within TA–67, they would either be destroyed by construction or diminished in value by the alteration of the area. If none of these resources are present, then no effect would be expected.

I.4.4.6 *Waste Management (Construction Refuse)*

Developing a new LLW disposal location at TA–67 would generate refuse from constructing the support facilities. The quantity is not known at present. This refuse would be recycled to the extent possible, and the remainder would be disposed of in the Los Alamos County Landfill. Waste from disposal cell construction would be managed at the location.

I.4.4.7 *Environmental Restoration*

Developing an LLW disposal area at TA–67 is not anticipated to have ER implications. However, developing in a new and uncontaminated location would create another area with permanent constraints on future uses due to waste buried there.

I.4.4.8 *Traffic*

If TA–67 were developed, the traffic would increase less than 1 percent for 1 to 2 years on Pajarito Road and West Jemez Road as construction materials and pre-engineered support structures were moved to the site and construction wastes were removed. Constructing new LLW disposal cells subsequently would have no impact on the flow of traffic on public roads.

I.4.5 Preferred Alternative—Develop Zones 4 and 6 at TA–54

The consequences of the Preferred Alternative, to develop Zones 4 and 6 in step-wise fashion moving westward from the present LLW disposal area in Area G, would be the additive consequences of those discussed separately for Zone 4 in section I.4.1 and Zone 6 in section I.4.2, except for noise. The consequences of noise are taken as the louder of the noise effects from Zone 4 or 6 at each of the receptor locations.

I.4.5.1 *Land Resources*

Land Use

Because the whole of Mesita del Buey has been identified for management of solid wastes, developing Zones 4 and 6 would not result in a change to the land use designation of research and development and waste disposal.

Visual Resources

New disposal cells would not be visible from Pajarito Road. The cells would be visible from the boundary of the San Ildefonso Pueblo, but not from the human habitations at White Rock, Los Alamos, Totavi, Otowi, or BNM.

Noise

The noise level to which people could be exposed varies with receptor location, as shown in Table I.4.5.1–1. The estimates shown represent the louder of the estimates from Tables I.4.1.1–1 (Zone 4) and I.4.2.1–1 (Zone 6) at each receptor location. Disposal cell construction in Zones 4 and 6 would be audible at the San Ildefonso Pueblo boundary, but not at the human habitations at Totavi and Otowi, which are much farther away than White Rock and the Los Alamos townsite. Noise levels at residential areas due to the excavation and construction activities would be audible, but within normal levels in White Rock, the Los Alamos townsite, and at the Royal Crest Trailer Park. Noise from cell construction could be audible above background at the roadway boundary to BNM, but not at the Visitors' Center nor in the developed campgrounds. The estimates presented are very conservative; in practice, the uneven terrain, intervening vegetation, and direction of air movement would further reduce the noise at receptor locations.

TABLE I.4.5.1–1.—*Sound Level Estimates[a] from Excavations/Construction in Zones 4 and 6 at Receptor Locations[b]*

ALTERNATIVE	OPERATORS, 3 to 6 ft (1 to 2 m) DISTANCE, dBA	ON-SITE PERSONNEL, 50 ft (15 m) DISTANCE, dBA	WHITE ROCK, dBA	ROYAL CREST TRAILER PARK, dBA	LOS ALAMOS TOWNSITE, dBA	BANDELIER NATIONAL MONUMENT, dBA	SAN ILDEFONSO PUEBLO BOUNDARY, dBA
Zones 4 and 6 Disposal Cell Excavation	90 to 113[c]	72 to 95	30 to 53	22 to 45	22 to 45	22 to 45	45 to 68
Normal Background	NA	NA	38 to 51	no data (assume 38 to 51)[d]	38 to 51	31 to 35	no data (assume 31 to 35)[d]

[a] Values calculated from standard noise ranges at 50 ft (15 m), using the inverse square relationship: sound level$_1$ - sound level $_2$ = 20 log r_2 r_1^{-1} where 1 and 2 represent two locations.
[b] Distances from residential areas shown in Table I.3.1–1.
[c] Standard construction equipment noise ranges (from Canter 1996).
[d] In these cases, noise levels were assumed to be the same as those measured in nearby locations. The noise level at the Royal Crest Trailer Park was assumed to be the same as that measured at the Los Alamos townsite, and the noise level at the San Illdefonso boundary is assumed to be the same as that at the adjacent BNM land (refer to Figure I.1.1–1).
NA = Not applicable

The sound levels at and near the excavation equipment are sufficiently high that operators would be provided with hearing protection. Hearing protection may be provided for other personnel in the vicinity of construction, as needed.

I.4.5.2 *Air Quality*

As discussed in section I.4.1.2, LANL personnel would use standard dust suppression methods. Excavating cells would not be expected to degrade the quality of air in residential areas.

The wood from trees cleared from Zones 4 and 6 would be chipped and burned or used as mulch on the site. The burning would be conducted under an open burning permit obtained from NMED, such that the air quality standards would not be violated. Trees would be cleared in a step-wise fashion, as disposal area becomes needed.

I.4.5.3 *Ecological Resources*

Flora and Fauna

Developing Zone 4 and then Zone 6 would require that most or all of the pinyon-juniper tree cover on the 41 acres (17 hectares) be removed; however, this would be done in a gradual manner as disposal space was needed. The wood would be chipped and burned or used as mulch on the site. This would change or eliminate bird and small mammal habitat in direct proportion to the acreage disturbed. The habitat change caused by removing 41 acres (17 hectares) of vegetative cover would be small compared to the available habitat remaining in the area, which measures hundreds of acres in size. Similar habitat is available at the North Site. Construction noise and activity would cause minor and short-term disturbance to wildlife utilizing adjacent habitat during the various development phases. Because the new disposal cells would only be fenced during the time that they are active, and the whole area would not be fenced, no new impacts are anticipated to the large game animals that utilize the area.

The cumulative impact of removing an additional 41 acres (17 hectares) of pinyon-juniper woodland when added to the 63 acres (25 hectares) removed (assuming comparable plant density) in achieving the current size of the Area G LLW disposal area should be small. Much of Mesita del Buey is likely part of the Pajarito Canyon watershed, which currently has approximately 1,900 acres (770 hectares) of pinyon-juniper woodland. This vegetation type is the most abundant on LANL, currently covering an estimated 13,000 acres (5,265 hectares), or slightly over 46 percent of LANL. The cumulative impact would be a decrease in about 104 acres (42 hectares) of pinyon-juniper habitat for the birds and small and large mammals that utilize this habitat type. This habitat is located in an area that has experienced fragmentation from past actions, and any contribution to fragmentation would be minor. When considering the abundance of this habitat on LANL as well as the region, cumulative biological and ecological effects would be small.

Threatened and Endangered Species

A peregrine falcon nest site is located more than 3 miles (4.8 kilometers) from both proposed expansion areas at TA–54. Peregrine falcons have a wide foraging area, typically up to 12.3 miles (19.8 kilometers) from their nest. The total amount of foraging habitat for this nesting location is 126,805 acres (50,722 hectares), not including developed areas. Some 41 acres (17 hectares), or less than 0.05 percent of possible foraging habitat for peregrine falcons could ultimately be lost due to tree removal, in the event that this Preferred Alternative is chosen (Keller and Bennett 1996). However, this loss would be gradual and would not result in an appreciable effect on this species. Cumulative effects would not change appreciably from current conditions.

I.4.5.4 *Environmental Justice*

The disposal area development would be visible from the pueblo boundary, and the noise from disposal cell excavations would be audible, should anyone be present at the boundary. However, the noise is not in the range considered harmful to human health.

I.4.5.5 *Cultural Resources*

DOE lacks information regarding the presence of TCPs on Mesita del Buey. In the absence of specific information on such resources, the potential consequences of developing Zones 4 and 6 on such resources can only be estimated qualitatively. If these resources are present within Zones 4 and 6, they would either be destroyed by construction or diminished in value by the alteration of the area. If none of these resources are present, then no effect would be expected.

A total of 15 archaeological sites would be affected or destroyed by constructing an LLW disposal facility at Zones 4 and 6. Although the cultural report and data recovery plan for Zone 4 has been accepted by the SHPO, that is not the case with Zone 6, as discussed in section I.4.2.5. The Zone 4 area north of the road, where there are no sites, could be developed first. Simultaneously, the approved excavation and data recovery plan could be initiated in Zone 4 south of the road. Before Zone 6 could be developed, DOE would prepare a proposal for mitigation of adverse effects to the eligible sites (a data recovery plan) and incorporate the concerns of the Accord Pueblos. The New Mexico SHPO would review the document prior to implementation of mitigation measures and be requested to concur in a determination of no adverse effect before the start of project activities.

I.4.5.6 *Waste Management (Construction Refuse)*

Waste from disposal cell construction (i.e., soil and rock) would be managed at the location (used for fill and for cover or disposed of). No other construction would be needed.

I.4.5.7 *Environmental Restoration*

All of TA–54 is considered a part of ER Operable Unit 1148. There would be no additional ER implications from disposing of LLW in Zones 4 and 6.

I.4.5.8 *Traffic*

As noted in section I.2.5, the only construction required to implement this alternative would be to fence cells being excavated and filled. Thus, developing the Preferred Alternative would not require construction materials to be transported to the site nor generate construction wastes to be removed from the site. There would be no effect on the flow of traffic on public roads.

I.4.6 Potential Accidents

The potential accidents identified are those that could take place during disposal cell construction and during support facility and infrastructure construction in the case of the TA–67 alternative. The consequences of construction accidents are injury or possibly death to one or more workers. The probability for such an accident is low where the amount of construction work required is small (i.e., disposal cell construction only), but increases with the increased amount of construction work. Thus, the probability of an accident would be greatest for the TA–67 development alternative, because it would require substantially more construction work.

During construction, the bounding case accident for a worker would be injury or death due to industrial accident. A piece of heavy equipment such as a crane could fall on a worker or a trench wall could collapse. Any industrial accident could cause injury or death to one or more involved workers. Uninvolved workers and members of the public would not be affected. The environment would not be contaminated. Working according to standard operating procedures, facility procedures, and worker training would decrease the probability of this accident.

Operational accidents and their consequences are analyzed in chapter 5 of volume I. Projected accident rates are also presented there.

I.4.7 Comparison of Environmental Consequences

The potential consequences of expanding LLW disposal in each of the alternative locations are summarized and compared in Table I.4.7–1. The consequences of the Preferred Alternative, developing both Zones 4 and 6, are the additive consequences of those associated with the two individual locations, except for noise where the louder of the noise estimates for Zone 4 and 6 is presented for each of the receptor locations. Similarly, the distance to various locations is taken as the closer of the two figures presented. The environmental consequences of the selected alternative, developing an additional area for LLW disposal, are included in chapter 5 (section 5.3) of volume I, along with the consequences of ongoing LANL operations in describing overall impacts of LANL operations.

TABLE I.4.7–1.—*Comparison of Environmental Consequences of Expanding Low-Level Waste Disposal in Alternative Locations*

	PREFERRED ALTERNATIVE			
FACTOR, MEASURE	**ZONE 4, TA–54**	**ZONE 6, TA–54**	**NORTH SITE, TA–54**	**TA–67**
Status (distance to and location of nearest residential area)	1.3 mi (2.1 km) White Rock	2.1 mi (3.4 km) White Rock	2.1 mi (3.4 km) White Rock	1.5 mi (2.4 km) Royal Crest Trailer Park
Distance to BNM Boundary	3.0 mi (4.8 km)	3.2 mi (5.1 km)	3.2 mi (5.1 km)	2.0 mi (3.2 km)
Distance to San Ildefonso Pueblo Boundary[a]	0.25 mi (0.4 km)	0.3 mi (0.5 km)	0.05 mi (0.1 km)	1.5 mi (2.4 km)
LANL Land Use Designation	no change in designation	no change in designation	no change in designation	designation changed to include LLW disposal
Visibility from Public Access Area	no change	no change	no change	increased visibility from Pajarito Road
Excavation and Construction Noise at Nearest Residential Area	may slightly exceed normal background level	may slightly exceed normal background level	may slightly exceed normal background level	equivalent to normal background level
Air Quality	dust and exhaust during disposal cell and shaft excavation, smoke from open burning of cleared trees	dust and exhaust during disposal cell and shaft excavation, smoke from open burning of cleared trees	dust and exhaust during disposal cell and shaft excavation, smoke from open burning of cleared trees	dust and exhaust during site and road development, then during disposal cell and shaft excavation, smoke from open burning of cleared trees
Ecological Resources (flora and fauna)	clear 24 acres (10 hectares), loss of pinyons and understory	clear 17 acres (7 hectares), loss of pinyons and understory	clear 49 acres (20 hectares), loss of pinyons and understory	clear 60 acres (24 hectares), loss of pinyon and ponderosa pine, juniper, and understory
Threatened, Endangered, and Sensitive Species	loss of < 0.1 percent foraging area; no appreciable effect on threatened peregrine falcon	loss of < 0.1 percent foraging area; no appreciable effect on threatened peregrine falcon	loss of < 0.1 percent foraging area; no appreciable effect on threatened peregrine falcon	loss of about 1.3 percent of roosting and foraging habitat; no appreciable effect on threatened Mexican spotted owl; may adversely affect potential nesting habitat desirability and usefulness to the species

TABLE I.4.7–1.—*Comparison of Environmental Consequences of Expanding Low-Level Waste Disposal in Alternative Locations*-Continued

FACTOR, MEASURE	PREFERRED ALTERNATIVE ZONE 4, TA–54	PREFERRED ALTERNATIVE ZONE 6, TA–54	NORTH SITE, TA–54	TA–67
Environmental Justice	development visible and noise audible at San Ildefonso Pueblo boundary	development visible and noise audible at San Ildefonso Pueblo boundary	development visible and noise audible at San Ildefonso Pueblo boundary	development not visible and noise not audible at San Ildefonso Pueblo boundary

Traditional Cultural Properties	no information available, any sites present could be destroyed or degraded	no information available, any sites present could be destroyed or degraded	no information available, any sites present could be destroyed or degraded	no information available, any sites present could be destroyed or degraded
Waste Management	no change	no change	no change	some construction refuse
Environmental Restoration	need to avoid exclusion area	no change	no change	no change
Traffic	no change	no change	no change	increase for 1 to 2 years due to construction
Accidents (industrial)	probability is low, consequence is injury or death to a worker	probability is low, consequence is injury or death to a worker	probability is low, consequence is injury or death to a worker	probability is higher (additional construction), consequence is injury or death to a worker

[a] Distance from the existing LLW disposal site in Area G to the San Ildefonso Pueblo boundary is 0.13 mi (0.2 km). Distance to human habitations at San Ildefonso Pueblo (Totavi) is 5 mi (8 km).

The greatest differences among the PSSC alternatives are due to the differences between TA–54 and TA–67.[8] That is, the TA–54 PSSC alternatives (Zone 4, Zone 6, North Site, and Zones 4 and 6) have very similar impacts; but each is very different from the TA–67 alternative. This is due primarily to the need to replicate at TA–67 much of the infrastructure that already exists at TA–54, including office space, showers, locker rooms, control rooms, personnel monitoring stations, a decontamination wash pad, packaging and inspection areas, fencing, utilities, and roads. Such infrastructure development would require substantially more construction and land disturbance to provide a comparable area for waste disposal. This level of construction at TA–67 would result in (as compared to any of the TA–54 alternatives) additional dust and exhaust (from construction) and smoke (from burning cleared trees), substantially greater loss of bird habitat (including potential roosting and forage-only habitat for the Mexican spotted owl), the potential to adversely affect the Mexican spotted owl (no effect to federally protected species is expected at any of the TA–54 alternative sites), greater waste generation, increased traffic during construction to establish the site infrastructure, and a greater likelihood of construction accidents (due to the additional construction). While the TA–67 location is slightly closer to the nearest residential area and to the nearest BNM boundary, it is much farther from the San Ildefonso Pueblo boundary, as compared to any of the TA–54 alternatives. Under all alternatives, the disposal cells would not be visible from inhabited areas, but the support structures would be visible from public access areas (such as Pajarito Road); the principal difference in visual impacts is due to the fact that TA–67 is not currently developed. Areas of relatively minor difference between the TA–54 alternatives and the TA–67 alternative are: noise from any of the TA–54 sites would be slightly above normal background at the nearest residential area, while noise from TA–67 would be equivalent to normal background levels at the nearest residential area; all of the alternative sites contain archaeological sites that would require data recovery plans or avoidance; no information exists regarding specific TCPs at any of the alternative sites; none of the alternative sites would be expected to disturb the sites of ER projects; and TA–67 development and operations would not be visible or audible at the San Ildefonso Pueblo boundary, but would be visible and audible from this boundary for all of the TA–54 alternative sites (although not from any San Ildefonso Pueblo residential areas).

---

8. TA–67 was selected to represent development of a new disposal site at LANL. While the specific characteristics of TA–67 may not be applicable to all potential sites, the majority of the differences in the impacts of TA–54 alternatives and the TA–67 alternatives are attributed to the need to establish an appropriate infrastructure to support waste disposal at TA–67 (as discussed in this section), and these types of differences would apply to other locations for a new disposal site. The possible existence of a fault in part of TA–67 may not be applicable to other sites.

APPENDIX I.A—*Scientific Names of Animals and Plants* (referred to by their common names in the text)

COMMON NAME	SCIENTIFIC NAME	STATUS
ANIMALS		
Black Bear	*Ursus americanus*	
Bobcat	*Felis rufus*	
Brush Mouse	*Peromyscus boylii*	
Colorado Chipmunk	*Eutamias quadrivittatus*	
Coyote	*Canis latrans*	
Elk	*Cervus elaphus* *Subspecies: candensis*	
Gray Fox	*Urocyon cinereoagenteus*	
Jemez Mountain Salamander	*Plethodon neomexicanus*	species of concern[a], state threatened[b]
Least Chipmunk	*Eutamias minimus*	
Little Brown Occult Bat	*Myotis occultus*	species of concern
Long-Tailed Vole	*Microtus longicaudus*	
New Mexican Meadow Jumping Mouse	*Zapus hudsonius luteus*	species of concern, state threatened
Mexican Spotted Owl	*Strix occidentalis lucida*	Federal threatened[c]
Montane Vole	*Microtus montanus*	
Mountain Lion	*Felis concolor*	
Mule Deer	*Odocoileus hemionus*	
Northern Goshawk	*Accipiter gentilis*	species of concern
Peregrine Falcon	*Falco peregrinus*	Federal endangered[d], state endangered[e]
Spotted Bat	*Euderma maculata*	species of concern, state threatened
Southwestern Willow Flycatcher	*Empidonax traillii*	Federal endangered, state endangered
VEGETATION		
Blue Grama	*Bouteloua gracilis* (H.B.K.) Lag.	
One-Seeded Juniper	*Juniperus monosperma* (Engelm.) Sarg.	
Pinyon Pine	*Pinus edulis* Engelm.	
Ponderosa Pine	*Pinus ponderosa* Laws. var. *scoparium* Engelm.	

[a] Species of local concern: Any species known to exist or potentially exist within the proximity of LANL lands and surrounding areas that are rare in numbers and/or occurrences and whose habitat requirements are very specific, rare to this area, or threatened in any way.
[b] State threatened: Any species whose prospects of survival or recruitment within the state are likely to become jeopardized in the near future.
[c] Federal threatened: Any species that is likely to become endangered within the foreseeable future throughout all or a significant portion of its range.
[d] Federal endangered: Any species that is in danger of extinction throughout all or a significant portion of its range.
[e] State endangered: Any species listed in the New Mexico endangered list because it is rare in numbers and/or occurrences and, without protection, its further existence in the state is in serious jeopardy.

APPENDIX I.B.—*Volatile Organic Contaminant Plume Constituents*

TA–54 MDA L Volatile Organic Contaminant Plume: Observed Maximum Concentrations During May 1997[a] with Modified EPA Method TO–14[b]

PART II
ENHANCEMENT OF PLUTONIUM PIT MANUFACTURING

II.1 INTRODUCTION

The draft SWEIS identified the Utilize Existing Unused Space in the Chemistry and Metallurgy Research (CMR) Building as the Project-Specific Siting and Construction (PSSC) Preferred Alternative for the proposed enhancement of plutonium pit manufacturing capability at LANL. However, as a result of delays in the implementation of the Capability Maintenance and Improvement Project (CMIP) and recent additional controls and operational constraints in the CMR Building (instituted to ensure that the risks associated with CMR operations are maintained at an acceptable level), the DOE has determined that additional study of methods for implementing the 50 pits per year production is warranted. In effect,

has postponed the decision to implement the pit manufacturing capability beyond a level of 20 pits per year (14 pits per year is the No Action level). The DOE believes it can expand the pit manufacturing capability to 20 pits per year at Technical Area (TA)–55 without significant infrastructure upgrades, as analyzed in this PSSC analysis, and still meet its near-term mission requirements. When any necessary additional studies are completed, DOE will provide the appropriate NEPA review, tiered from this SWEIS, to implement the pit manufacturing capability beyond the 20 pits per year capacity. This postponement does not modify the long-term goal announced in the Record of Decision (ROD) for the *Stockpile Stewardship and Management Programmatic Environmental Impact Statement* (SSM PEIS) (DOE 1996) (up to 80 pits per year using multiple shifts). For completeness and to bound the impacts of implementing pit production at LANL, the "CMR Building Use" Alternative is still included in the Expanded Operations Alternative. However, the Preferred Alternative would only implement pit manufacturing at a level of 20 pits per year. Also, the ROD for the SWEIS would only include a decision regarding the operations to implement the pit production mission at LANL for up to 20 pits per year.

II.1.1 The Role of the Enhancement of Plutonium Pit Manufacturing Project-Specific Siting and Construction Analysis in the Site-Wide Environmental Impact Statement

This PSSC analysis addresses the proposed enhancement of plutonium pit manufacturing capability at LANL. It examines the siting and construction alternatives for this project, supplementing the description and analysis presented in volume I of this SWEIS. The Utilize Existing Unused Space in the CMR Building ("CMR Building Use") Alternative from this PSSC analysis is included as one of the activities in the Expanded Operations Alternative in volume I of the SWEIS. The differences between the impacts of this alternative for pit manufacturing and the impacts of the other alternatives considered are discussed in chapter 5, section 5.3, of volume I. For the key facilities involved, construction activities examined in this PSSC and the subsequent operations (described in volume I, chapter 3, section 3.2) form a substantial portion of the Expanded Operations Alternative of the SWEIS.

The focus of this PSSC analysis is the siting and construction related to the enhancement of pit

PSSC Alternatives for Enhancement of Plutonium Pit Manufacturing

- ***Utilize Existing Unused Space in the CMR Building****—DOE would make existing unused nuclear space in the CMR Building operational and would move some of the existing activities in TA–55–4 to the CMR Building in TA–3 to make adequate space in TA–55–4 for plutonium pit manufacturing activities. DOE also would establish a dedicated transportation corridor between TA–55 and TA–3.*
- ***Brownfield Plutonium Facility****—DOE would build a new plutonium-qualified facility in a developed area near TA–55–4 and within the existing fence line at TA–55. As with the "CMR Building Use" Alternative, activities currently located within TA–55–4 would be moved to this new facility to make space available in TA–55–4 for plutonium pit manufacturing. The transportation corridor also could be constructed under this alternative.*
- ***Add-on to the TA–55–4****—DOE would enlarge the existing TA–55–4 by adding new nuclear space onto this building. Because this adds space to TA–55–4, it may not be necessary to relocate activities currently located in TA–55–4 to this new nuclear space. Rather, this space may be designed specifically for, and house, the expanded pit manufacturing operations. The transportation corridor also could be constructed under this alternative.*

manufacturing. The environmental impacts of operating pit manufacturing facilities are included in chapter 5 of the SWEIS, volume I. The air emissions, worker doses, and certain other parameters associated with pit manufacturing operations would depend on the number of pits manufactured. The consequences to members of the public, however, are dominated by the location of the operations because distance from the operations to the public affects the magnitude of impacts. (Note that the operational impacts related to pit production are small relative to other operational impacts, as discussed in volume I, chapter 3, section 3.6.)

This arrangement of information and analysis allows DOE to "zoom in" on aspects of this project that require more detailed description and analysis, while maintaining the clarity of volume I. The organization of this PSSC is complementary to the organization of information in volume I. The siting and construction information presented here is additional to the operational information provided in volume I and is pertinent to understanding the actions and alternatives described in that portion of the SWEIS. The siting and construction consequences from the "CMR Building Use" Alternative described in this PSSC analysis are included in those described in volume I, chapter 5, for the Expanded Operations Alternative to provide a complete and bounding analysis of the impacts of those operations.

Section II.2 of this PSSC analysis identifies alternative locations at LANL where the additional pit manufacturing capacity could be developed. Section II.3 contains more detailed information about the environmental conditions at each of these locations than is presented in volume I, chapter 4, of the SWEIS. Section II.4 presents the environmental consequences of the construction phase only for enhanced pit manufacturing, and section II.5 addresses the consequences of a potential construction accident. Operational impacts, including operational accidents, are addressed in volume I. The entire SWEIS, including this PSSC analysis, is intended to provide a complete and bounding NEPA analysis of pit fabrication at LANL.

II.1.2 Background Information

In September 1996, DOE issued the SSM PEIS (DOE 1996). Based on this PEIS, DOE issued a ROD on December 19, 1996, that selected LANL as the site for the fabrication of weapon components referred to as pits. The SSM PEIS and its ROD established pit production at LANL. It is expected that up to 50 pits will be manufactured per year under routine operations with a maximum capacity that could produce up to 80 pits per year (with multiple-shift operations). For this reason, the Expanded Operations Alternative includes production of up to 80 pits per year, as well as all related support operations for this capability.

As noted in the description of the Expanded Operations Alternative, this production level of pit manufacturing necessitates operations that, together with other ongoing operations, cannot be accommodated within the available floorspace in the LANL Plutonium Facility at TA–55 (Building TA–55–4). DOE and LANL have identified that 15,300 square feet (1,425 square meters) of additional floorspace is needed to fully support this level of operation (LANL 1997). The Expanded Operations Alternative description and analysis includes the establishment and use of this needed floorspace. The establishment of this additional floorspace (through allocation of existing space or construction of new space) is addressed in detail in this PSSC analysis, as is the utilization of the space (including a discussion of functions that could be performed in this space).

II.1.3 Material Flows Associated with the Pit Manufacturing Capability

The relationship between the manufacture of pits and other related operations at LANL is presented in Figure II.1.3–1.[1] This diagram reflects the types of material flows associated with these operations. A more detailed description of these operations is presented in volume I, chapter 3, of the SWEIS. The manufacture of pits involves the generation of samples for analysis; generation of residues for stabilization or recovery; generation of waste for treatment, storage, and disposal; and storage and handling of plutonium in solid and liquid forms.

The following existing capabilities are essential to support pit manufacturing operations as well as other ongoing operations at LANL: TA–3 capabilities for analytical chemistry and nonnuclear parts; TA–50 and TA–54 waste treatment, storage, and disposal capabilities; TA–55 capability for residue processing, particularly aqueous and pyrochemical processing; TA–55 capability for storage and handling of plutonium in several forms; and TA–8 capability for radiography. The locations of the TAs that support pit manufacturing operations are shown in Figure II.1.3–2. These capabilities support ongoing operations throughout LANL, and therefore, their continued viability is essential to many missions and programs at LANL. DOE does not currently propose to replace these capabilities. The alternatives in this PSSC analysis maximize use of existing capabilities in order to minimize the environmental effects of establishing the pit production operations identified above. Construction and reconfiguration activities to enhance pit manufacturing are only anticipated to occur at TA–55 and, for a bounding analysis, at the CMR Building under the "CMR Building Use" Alternative.

II.1.4 Laboratory Floorspace Requirements

Increased nuclear materials processing floorspace and analytical chemistry space are

---

1. In addition to pits returned from storage or the stockpile, feed material for pit production could also come from other portions of DOE's plutonium inventory. The diagram reflects only pit returns as feed material for the sake of simplicity.

FIGURE II.1.3–2.—*Location of LANL Operations that Support Pit Manufacturing.*

required to meet reasonably foreseeable pit manufacturing requirements. Two steps were involved in determining the floorspace requirements. First, subject matter experts provided the total floorspace that their capability would require based on the projected requirements, without regard to the final location of the program or function. Results of this analysis indicated that approximately 15,300 square feet (1,425 square meters) were required in addition to floorspace currently available in TA–55–4 (see Table II.1.4–1). Second, the following criteria were employed to select the functions that could be relocated from existing space in TA–55–4 in order to make space available for pit manufacturing:

- Total floorspace would fulfill anticipated functional requirements.
- Only liquid waste and residues generated in large volumes at the additional space facility would be low-level radioactive liquid waste. (This can be sent to TA–50 for treatment.)
- Major equipment that is integral to the TA–55–4 plutonium infrastructure would not be moved from TA–55–4.
- Both locations should dedicate space to materials handling and waste management functions.
- Functions, such as plutonium-238 operations, that would require extensive decontamination would not move.
- Additional support functions that specific capabilities require would be moved if the capability is moved.

These criteria are consistent with the following two basic concepts: (1) identifying capabilities that can most easily be separated from the current TA–55–4 infrastructure and remaining capabilities and (2) reconfiguring TA–55–4 to provide adequate contiguous space to accommodate the remaining capabilities such as the expanded pit manufacturing activities.

With the information and criteria above, the floorspace allocations for operations and support functions were determined and are shown in Table II.1.4–1. Under these criteria, all or part of the capabilities marked with a superscripted letter "a" in Table II.1.4–1 could be conducted in the additional space. The functions analyzed for potential relocation in this PSSC analysis were selected to be representative of the functions that could move and to bound the potential impacts of the Expanded Operations Alternative.

The risks and hazards associated with each of these functions that are candidates for the additional space are essentially identical. They are driven by the type and form of the material (plutonium oxide or metal in almost all cases), the nature of the operations (physical manipulation, destructive and nondestructive analytical work, solid chemistry, and aqueous chemistry in small quantities), and the nature of the facility and equipment (which is driven by current design and other safety-related standards associated with plutonium operations). The one exception to this statement is the Special Recovery Line, which includes the capability to handle small quantities of tritium contamination (a different radioactive material than is associated with the rest of the materials that could transfer to the additional space) of plutonium parts (LANL 1997). Because the hazards associated with them are essentially the same for all of the functions that are being considered, the question of exactly which process(es) might be moved is not important to the analysis within this document. In other words, the operational impacts of the alternatives addressed in this PSSC analysis (discussed in volume I, chapter 5) are driven by the location of the operations, not the differences between those operations being considered to move to that location. For the purposes of this document, it is assumed that pit surveillance (as well as metallography associated with this function), pit disassembly for manufacturing feedstock, about 50 percent

of the actinide research and development and the Special Recovery Line would constitute the functions that would be moved. Based on the quantities and types of materials involved, these processes bound the materials and risks for the functions being considered to move to the additional space.

The enhancement of pit manufacturing operations would require improvements in infrastructure, rearrangement of processes to optimize material flows, and equipment purchases so that LANL could provide a maximum capacity of up to 80 pits per year (using multiple shift operations) for the enduring nuclear weapons stockpile. However, pit manufacturing would not be the only function at LANL that requires dedicated floorspace in a nuclear materials facility. Other functions currently exist at TA–55–4 and must continue for the foreseeable future. These functions, their floorspace requirements in TA–55–4, and additional space are outlined in appendix II.A.

II.1.5 Capability Maintenance and Improvement Project

The CMIP is the name of the construction project under which the enhancement of pit manufacturing would occur. The CMIP is a construction project that consists of two parts. The capability maintenance activities within this project are necessary to provide for the continued viability of several facilities, as discussed in volume I. These include TA–55 and the Sigma Building. These activities are included in all of the SWEIS alternatives described in volume I because they are necessary to maintain existing capabilities. The SWEIS analyses of these aspects of the CMIP are addressed in chapter 5 of volume I for all alternatives.

Alternatives that DOE could develop for creation of adequate additional space to accommodate pit production are presented in section II.2 of this PSSC analysis. As described earlier, modifications to TA–55–4 would be consistent with the following concepts: (1) identifying for possible relocation those capabilities that can most easily be separated from the TA–55 infrastructure and remaining capabilities and (2) providing adequate space within TA–55 to accommodate the remaining capabilities, including the enhanced pit manufacturing activities.

II.2 SITING AND CONSTRUCTION ALTERNATIVES

This section discusses alternatives for the construction of adequate additional space to accommodate pit production in addition to the other activities described in the Expanded Operations Alternative. Because of the potential transportation and handling implications of moving materials from TA–55 to the CMR Building, options for transporting special nuclear materials (SNMs) are discussed also. The options for transporting SNMs are applicable to each of the alternatives.

The typical No Action Alternative regarding this project (that is, not enhancing the existing capability), is discussed in the SWEIS No Action Alternative in volume I, and that discussion is not repeated here.

Conceptual locations have been identified for the Brownfield Plutonium Facility and the Add-on to TA–55–4 alternatives based on the conceptual operational requirements of the pit manufacturing capability provided in the SSM PEIS. These conceptual requirements have been used to broadly define facility size and category, utility needs, and other possible infrastructure characteristics. This information has been generally reviewed in the context of LANL's siting criteria and construction codes. The resulting locations are the product of this conceptual analysis.

II.2.1 Alternatives Analyzed in Detail

The text box on page II–2 briefly describes the three alternatives analyzed in detail. This section provides further information on these alternatives. As noted in these descriptions, pit manufacturing would continue during these construction activities by phasing construction. This approach allows for continuous support of missions throughout the construction activities.

II.2.1.1 *Utilize Existing Unused Space in the CMR Building Alternative*

Only two existing facilities at LANL are qualified to undertake the types of operations described in appendix II.A of this PSSC analysis: TA–55–4 and the CMR Building in TA–3. As noted previously, TA–55–4 does not currently have adequate available space. However, the CMR Building has two wings available and another wing that may become available in time to support these needs. These three wings are essentially equivalent, and would have almost identical construction and operational impacts if utilized.

This alternative is distinct from the others in that it does not require construction of new nuclear facility floorspace; rather, the construction project would focus on making existing nuclear facility space operational. Additionally, the majority of the construction involved is within existing facilities (which substantially reduces disturbance of land beyond the existing disturbance). Given that current employee office space is very limited at TA–55 and makes extensive use of portable trailers, it is reasonably foreseeable that a new office support facility could be constructed; thus, creation of this office space is included in the analyses for this alternative. The size and location of such a facility would likely be limited to currently developed areas. Operationally, the potential for transportation on public roads, as well as material handling volume and risk, are more substantial for this alternative than the alternatives discussed in sections II.2.1.2 and II.2.1.3. This alternative poses minimal potential for biological or cultural effects, and there would be no addition to the potentially contaminated space in either TA–55 or the CMR Building (i.e., uses existing nuclear space). Additionally, facility modifications under this alternative would generate transuranic (TRU)[2] waste and low-level radioactive waste (LLW)[3] (because these modifications would occur within the nuclear facility), which would require treatment and disposal.

The above discussion reflects an endpoint achievement in pit manufacturing capacity at TA–55–4. DOE would achieve this capacity in a phased manner. First, additional maintenance and equipment procurement would be conducted in TA–55–4 to support continued pit manufacturing at the existing capacity of about 14 pits per year (this is part of all SWEIS alternatives). Secondly, construction would be initiated to complete refurbishment of TA–55–4 for long-term viability of the facility in support of all missions: replacement of aged analytical chemistry support equipment and improvements to nonnuclear support facilities. By completion of the second phase, it is expected that an intermediate pit manufacturing capability of 20 pits per year at TA–55–4 would be achieved through use of the upgraded facilities and efficiencies gained in manufacturing operations. The final phase would be transfer of activities to the CMR Building, followed by modification of TA–55–4

2. TRU wastes contain a transuranic radionuclide with a half-life greater than 20 years and alpha activity of 100 nanocuries per gram (nCi/g) or greater at the time of measurement, excluding naturally occurring and depleted uranium, spent nuclear fuel, and high-level waste.

3. LLW contains radioactivity, but is not classified as high-level waste, TRU waste, spent nuclear fuel, or "11e(2) byproduct material" as defined by DOE Order 5820.2A, *Radioactive Waste Management*.

to provide for pit manufacturing at TA–55–4, as described above. The analyses of the "CMR Building Use" Alternative bound the potential risk to workers and the public from this phased approach.

Transportation Corridor

Transportation of SNM among the facilities at LANL would increase under the Expanded Operations Alternative. The transportation of samples between the CMR Building and TA–55–4 would also increase substantially (as described in the Expanded Operations transportation analysis). These shipments typically would require specially designed packaging and vehicles or road closures. In this case, total shipments between TA–55 and the CMR Building would be expected to increase by approximately 500 shipments of SNM per year (see appendix F in volume III). Road closures would occur more frequently.

In order to minimize impacts to the public (ranging from transportation-related risks to inconvenience), a restricted-access road between TA–55 and TA–3 (Figures II.2.1.1–1 and II.2.1.1–2) is proposed. This road would be developed on an existing dirt road just off of the existing public road. It would be utilized for all SNM shipments between TA–55 and the CMR Building. In addition to removal of vegetation, filling the road bed and paving the road, fences, gates, lights, towers, and other physical security structures would be constructed within the corridor. This road would not be constructed for the 20 pits per year rate.

In order to ensure that the potential impacts of the Expanded Operations Alternative are bounded, the transportation analysis in volume I includes transportation of these materials on public roads utilizing appropriate packaging to minimize road closures. The Expanded Operations Alternative (volume I, chapter 5, section 5.3.10) also includes the impacts of building the dedicated road. The resulting analysis is thus conservative in terms of public risk due to transportation accidents and in terms of public radiation exposures associated with routine shipments.

Inclusion of the "CMR Building Use" Alternative in the SWEIS

The "CMR Building Use" Alternative from this PSSC analysis is included in the SWEIS Expanded Operations Alternative and its associated impacts analysis. The "CMR Building Use" Alternative for pit manufacturing is to utilize existing unused space in the CMR Building (moving activities from TA–55–4 to CMR to make adequate space in TA–55–4 for plutonium pit manufacturing activities) and use a dedicated restricted access road (with minimal environmental impacts) to mitigate the impacts to the public related to transportation between TA–55 and the CMR Building.

II.2.1.2 *Brownfield Plutonium Facility Alternative*

In this alternative, DOE would build a new plutonium-qualified facility in a developed area near the existing Plutonium Facility at TA–55, hence, the use of the term "Brownfield." This stand-alone facility would take about as long to build and start up as a facility at an undeveloped or "Greenfield" site. A Greenfield facility, however, would require additional nonnuclear space (staging and storage, measurement equipment, etc.) as well as nuclear space (operational space); whereas, the Brownfield facility would be able to take advantage of some infrastructure at the existing TA–55 facility and thus, would likely require slightly less total floorspace and less total acreage than a Greenfield site. The Brownfield Plutonium Facility would have a new parking lot, new cold laboratory, low-level radiography, and support space. Approximately 15,300 square feet (1,425 square meters) of new laboratory floorspace would be required for this facility. A new office support facility could be required in the future and is analyzed as part of this

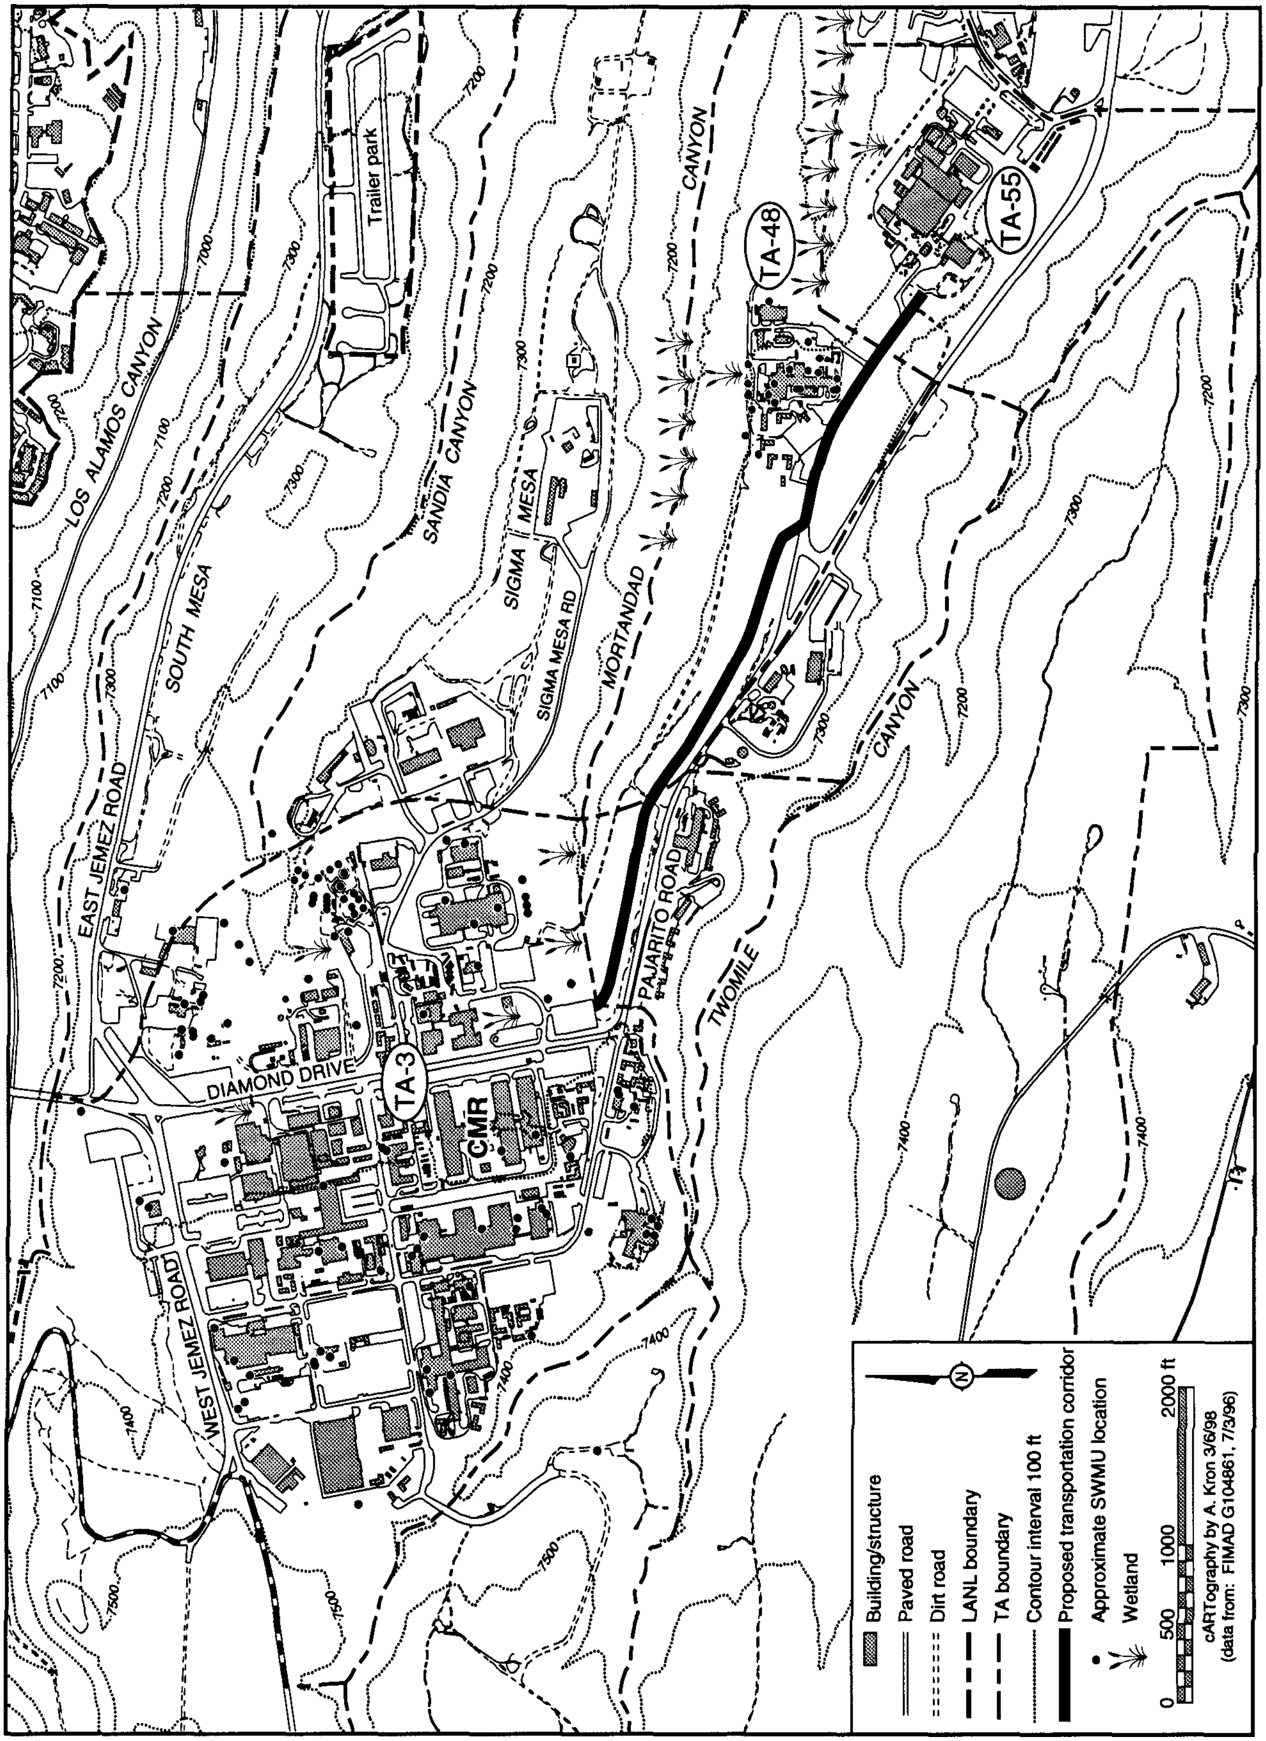

FIGURE II.2.1.1–1.—*Location of Proposed Transportation Corridor.*

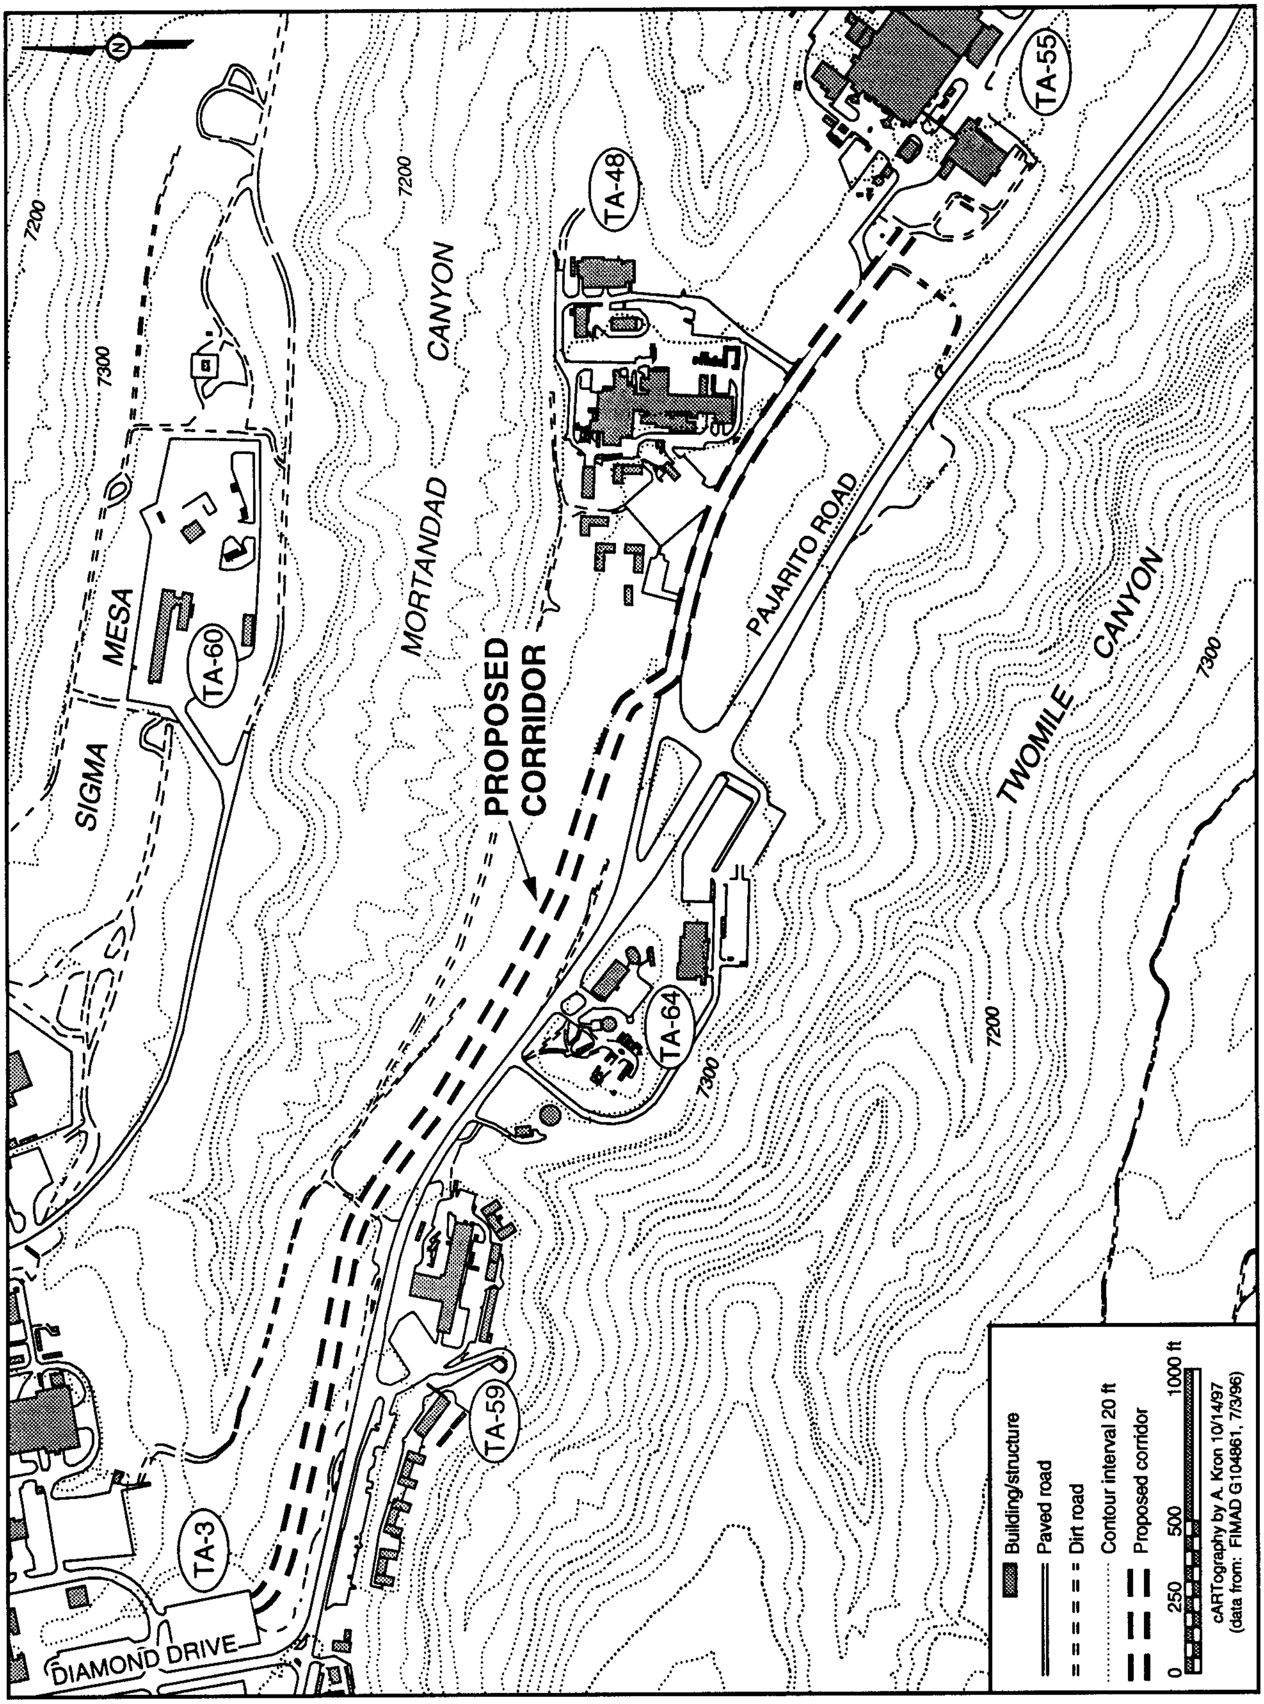

FIGURE II.2.1.1–2.—*Detailed Location of Proposed Transportation Corridor.*

alternative. This alternative includes a dedicated transportation corridor to be constructed between TA–55 and the CMR Building to provide analytical chemistry support to TA–55 pit manufacturing operations. The additional transportation options discussed in section II.2.1.1 also would be considered under this alternative.

As with the "CMR Building Use" Alternative for enhanced pit manufacturing, the increased pit manufacturing capacity would be phased under this alternative. The analysis of this alternative bounds the impacts of the phased implementation, and the operations impacts analyzed in volume I, chapter 5, bound the operational impacts of the phased implementation.

Conceptually, the Brownfield Plutonium Facility could be constructed just south and west of Buildings 1 and 2 within an existing protected area at TA–55 (Figure II.2.1.2–1). Although the facility itself is within the TA–55 fence line, the fencing and security system may have to be moved to provide adequate buffer between the building and the fence. In order to provide the operational space required (see Table II.1.4–1) under this alternative, this stand-alone facility would need to contain approximately 15,300 square feet (1,425 square meters) of designated nuclear laboratory space; it is assumed that this space would become contaminated during operations, creating a liability for eventual cleanup. The required utilities would be routed to this stand-alone facility from nearby utility corridors. The facility waste streams would be routed to nearby waste collection lines. Most transportation of materials would occur within the existing protected area at TA–55, and access control would be managed using existing or slightly modified security fencing and equipment. This alternative would minimize transportation of materials between the CMR Building and TA–55. Potential environmental advantages for this alternative would include minimizing transportation risks and minimizing development in currently undeveloped areas (less potential for cultural and biological impacts); however, it would create additional nuclear facility space that would potentially be contaminated (and have the liability for eventual decontamination and decommissioning).

II.2.1.3 *Add-On to the TA–55–4 Alternative*

Construction to add plutonium-qualified space to the existing plutonium facility at TA–55 is also considered reasonable. Because this alternative would take maximum advantage of the existing TA–55 facility infrastructure (i.e., utilities, structural support, vaults, alarm systems, etc.), it would require less total development than the Brownfield site to provide the same operational floorspace. This facility also may have low-level radiography as well as a new cold laboratory, and may require office support space (thus, construction of this office space is analyzed as part of this alternative).

Based on a conceptual siting, the TA–55 add-on plutonium facility could be located directly adjacent and along the northeastern wall of TA–55–4 between Buildings 42 and 8 (Figure II.2.1.3–1). The add-on plutonium facility would house approximately 15,300 square feet (1,425 square meters) of nuclear laboratory space. The infrastructure necessary to support the pit manufacturing capabilities under this alternative would be provided by the existing, or slightly modified, TA–55–4 Plutonium Facility. The utilities required for operations within the add-on facility would be provided by extending, and tying into, utility infrastructure already existing in TA–55–4. Material handling and movement would occur within TA–55–4, and the add-on facility and access control would be managed by using the existing TA–55–4 Plutonium Facility security systems.

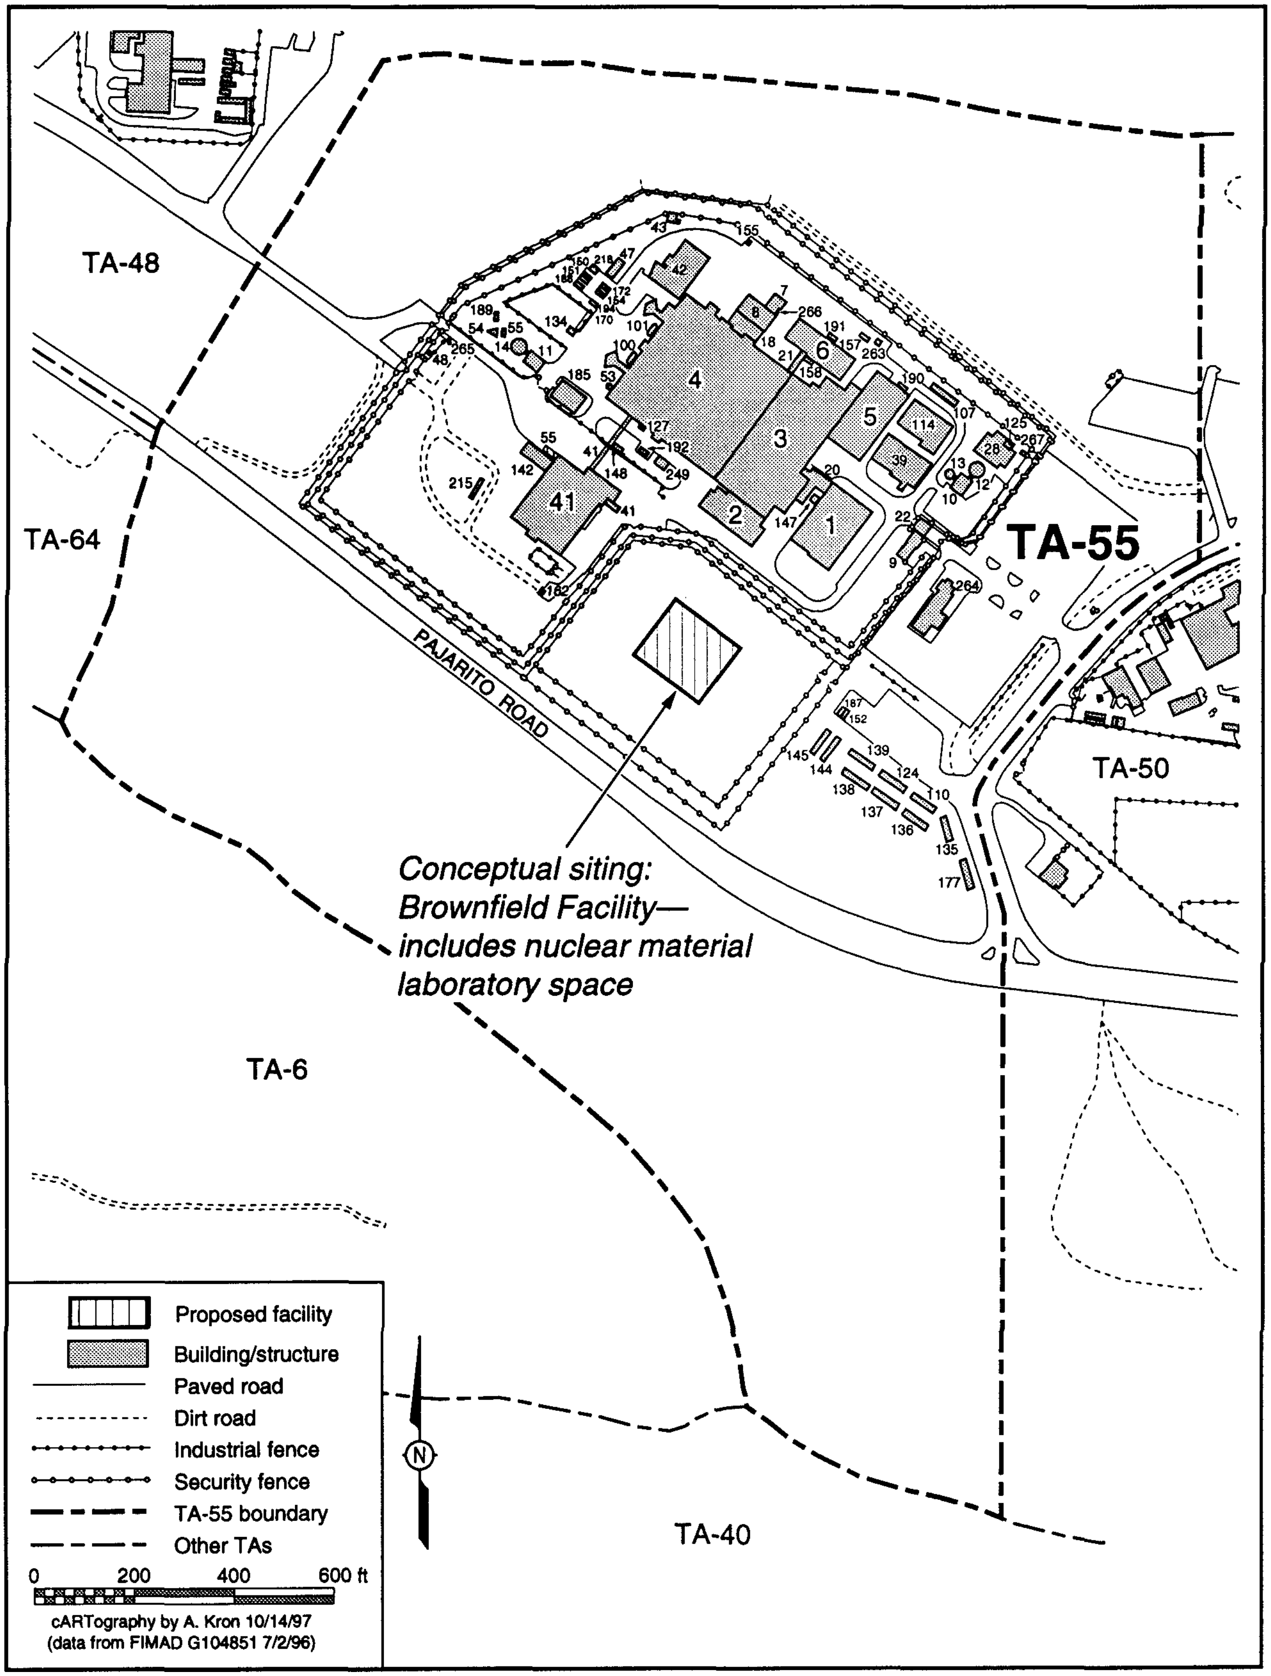

FIGURE II.2.1.2–1.—*Conceptual Location of the Brownfield Facility.*

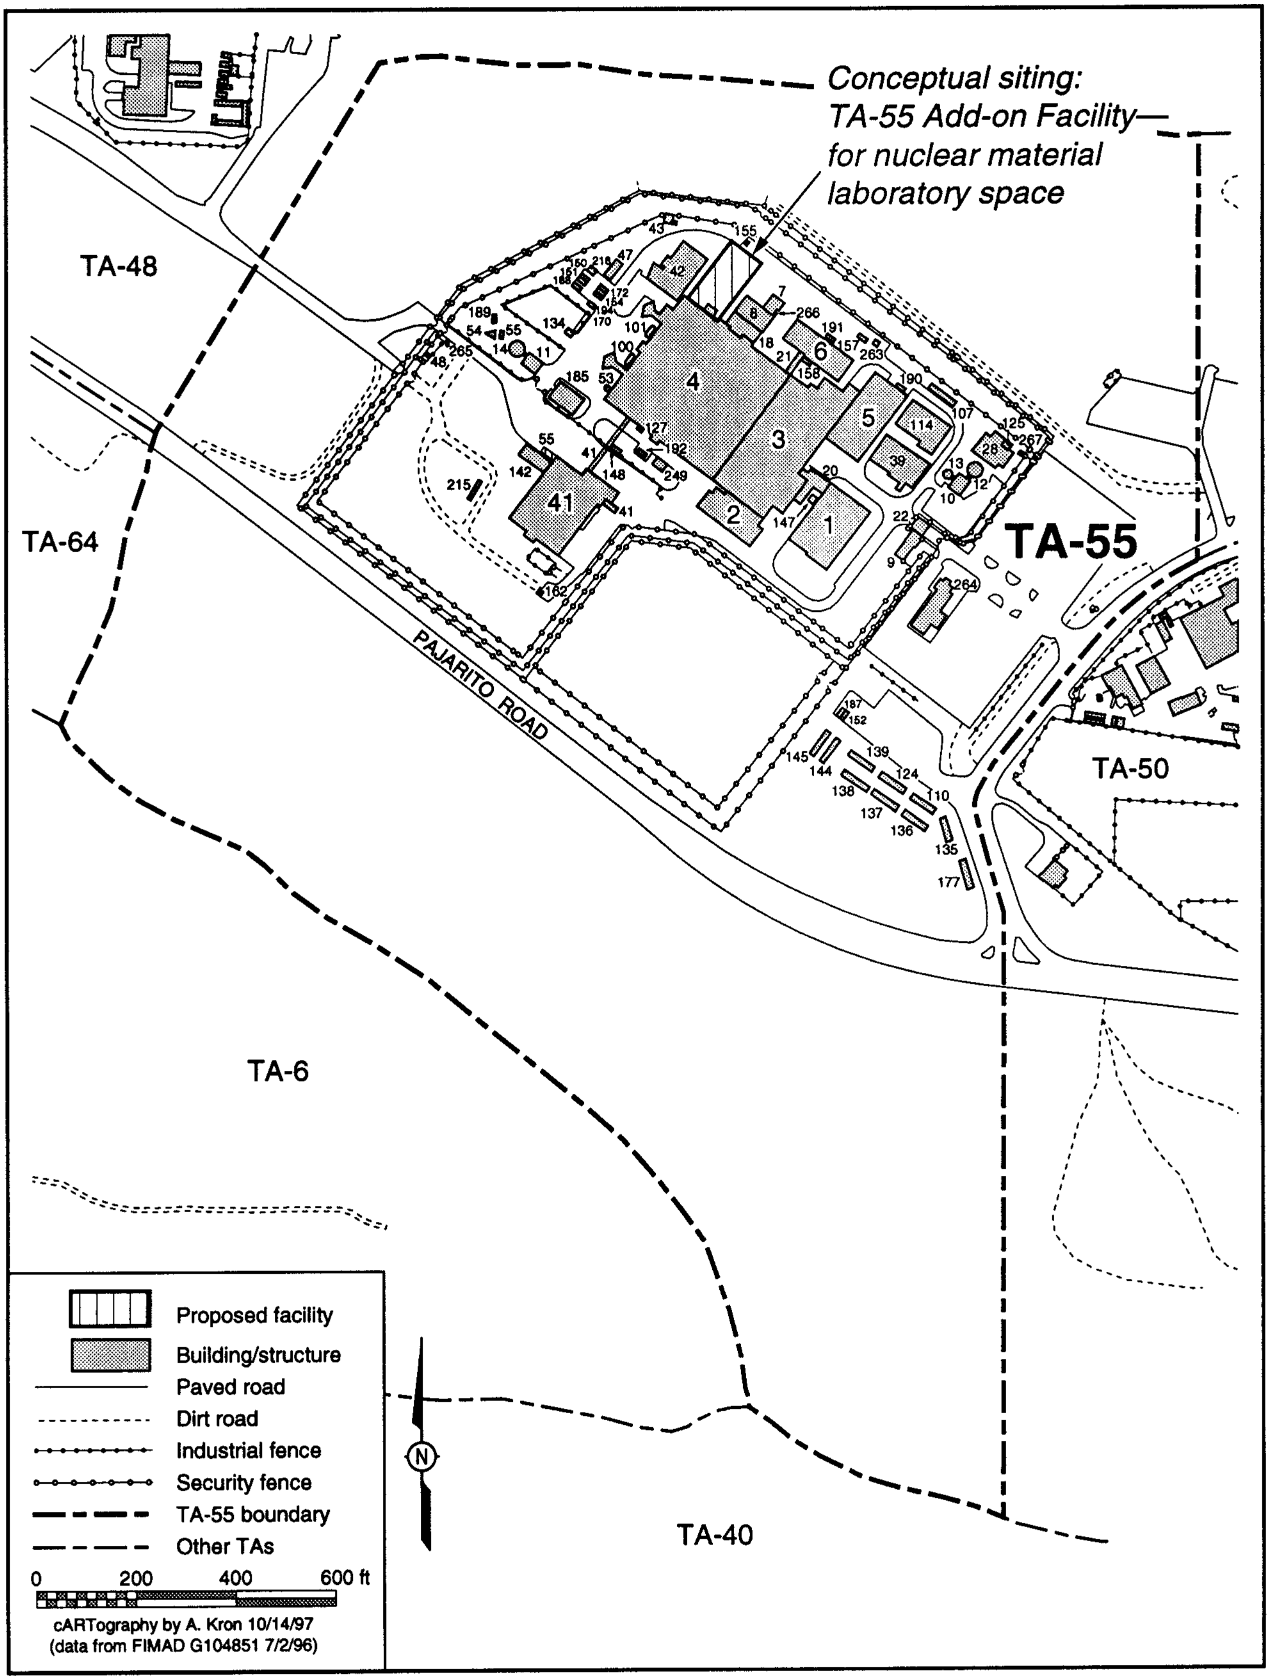

FIGURE II.2.1.3–1.—*Conceptual Location for the Add-On Facility.*

The add-on facility may not require relocation of current TA–55–4 operations. While this is an option that would be implemented in a phased manner (as discussed in the other two alternatives), it also is possible to maintain and operate existing activities in TA–55–4 as a new pit production facility is built within the add-on facility (again, this may also utilize a phased approach that increases the capacity of the existing capability up to 20 pits per year). Once the add-on facility was completed and functioning under this option, the activities in TA–55 would be expanded and rearranged within TA–55–4 to meet projected floorspace requirements. As with the other alternatives, the analysis includes all construction operations (under either of the alternative options), and the analysis of operations discussed in volume I, chapter 5, bounds the operations of the phased approach. This alternative would minimize transportation between TA–55 and the CMR Building (the same as for Brownfield). This alternative includes a dedicated transportation corridor to be constructed between TA–55 and TA–3 to provide analytical chemistry support to TA–55 pit manufacturing operations in the add-on facility. However, the additional transportation options discussed in section II.2.1.1 also would be considered under this alternative. This facility would create additional contaminated space. This alternative has essentially the same environmental impacts as the Brownfield facility.

II.2.2 Alternatives Not Examined in Detail

II.2.2.1 *Eliminate Existing Capabilities*

Existing plutonium facilities and capabilities at LANL are needed to support ongoing missions. Many of the capabilities that currently exist are essential to successfully support ongoing programmatic missions and implement the SSM PEIS decisions and cannot be eliminated (for example, aqueous and pyrochemical recovery and stabilization process, storage and handling of plutonium, plutonium metallurgy, analytical chemistry, and nondestructive analysis). Other nuclear facility capabilities are critical to ongoing missions at LANL, and there has been no DOE programmatic determination to cease or transfer these responsibilities to another site. Hence, the elimination of existing capabilities at LANL to make space available for enhanced pit manufacturing is not considered reasonable. For these reasons, an elimination alternative is not examined further.

II.2.2.2 *Greenfield Plutonium Facility*

An alternative to construct a new facility or facilities at an undeveloped location at LANL also was considered but dismissed from detailed evaluation. Such a facility would have to be largely self-sufficient and could take little advantage of existing infrastructure available at a developed site (replication of such infrastructure would mean a facility with far more total floorspace than the minimum required to perform the operations). Under such an alternative, site disturbance would be extensive (roads, parking areas, fences, utilities, administrative offices, etc.) with the potential for affecting biological, visual, and/or cultural resources. Such an action also would add substantially to the operating nuclear space in the weapons complex and at LANL at a time when DOE is trying to minimize this type of space (and thus, minimize the eventual liability for decommissioning of contaminated space). The time required to build and start up such a facility is extensive. There are no programmatic, environmental, or other advantages to undertaking this type of action beyond those represented in the alternatives described in section II.2.1. Transportation, material handling, and other issues are no different for this alternative than are represented in the other alternatives. Because there are no potential advantages to undertaking a

Greenfield Plutonium Facility, and there are additional unique environmental impacts associated with disturbing an undeveloped site, this alternative is not considered reasonable for detailed analysis.

II.2.2.3 *Other Existing Space*

While there may be other facilities with existing available space at LANL, with the exception of existing unused plutonium-qualified space at the CMR Building, this space does not meet current standards for supporting plutonium operations. Substantial upgrades to such facilities would be required to allow for their use in plutonium operations. By the nature of requirements for plutonium facilities, these upgrades would be so intrusive and complex that they would be similar in duration to the Brownfield Alternative. Additionally, such facilities are farther away from the existing infrastructure at TA–55 than is examined in the Brownfield Alternative, and so additional transportation risks would be incurred in this event (as compared to Brownfield). This alternative would have no programmatic or environmental advantages over the Brownfield Alternative. As such, this alternative is not considered to be distinct from the Brownfield Alternative and is not analyzed.

II.3 AFFECTED ENVIRONMENT

This section does not repeat information that is presented in volume I, chapter 4; it focuses on alternative-specific information that is needed to illuminate the differences among alternatives. Table II.3–1 identifies the environmental resources common to this PSSC analysis and volume I, along with their location in both documents. Table II.3–2 identifies environmental resources that are not discussed in this PSSC analysis, provides information about why they are not discussed, and identifies the locations of the discussions in volume I, chapter 4.

TABLE II.3–1.—*Potential Environmental Resource Issues Addressed in Volume I and This PSSC*

Environmental Justice	Volume I, section 4.7 and PSSC Analysis, section II.3.6
Human Health	Volume I, section 4.6 and PSSC Analysis, section II.3.7
Environmental Restoration and Waste Management	Volume I, sections 2.1.2.5 and 4.9 and PSSC Analysis, section II.3.8

II.3.1 Land Resources

II.3.1.1 *Land Use*

TA–55 and TA–3 have been designated for research and development land use purposes, as has the land within the neighboring TAs, including TA–48, TA–60, and TA–59. The majority of the land within TA–55 and TA–3 is highly developed industrially. TA–55 is located on Mesita del Buey, which is a narrow southeast-trending mesa about 2.5 miles (4 kilometers) long. The CMR Building is located in TA–3 about 1.2 miles (2 kilometers) west of TA–55 on South Mesa. The locations of TA–55 and TA–3 are shown in Figure II.1.3–2. Currently undeveloped land within the vicinity of TA–55, including that along the proposed transportation corridor, is open to wildlife use. It is not considered to be the highest quality

TABLE II.3–2.—*Potential Environmental Resource Issues Addressed Only in Volume I*

ENVIRONMENTAL RESOURCE	REASON NOT ADDRESSED IN THIS DOCUMENT	LOCATION OF DISCUSSION
Visual Resources	Any major construction would occur in developed industrial areas.	Chapter 4, section 4.1.2
Parks; Forests; Conservation Areas; Wetlands; and Areas of Recreational, Ecological, or Aesthetic Importance	None of these resources is located in any of the areas under consideration.	Chapter 4, section 4.1
Geology and Soils	Alternatives would involve the same types of surface soils and the same underlying Bandelier Tuff (Nyhan et al. 1978).	Chapter 4, section 4.2
Water Resources	None of the alternatives would affect water resources. Any modifications to runoff patterns would be minor relocations.	Chapter 4, section 4.3
Socioeconomic Conditions	Fewer than 140 workers would be required to implement the Preferred Alternative during times of peak labor demand. Construction projects associated with any of the alternatives would be approximately 4 years in duration, and the number of potential workers is very small compared to the population base in northern New Mexico.	Chapter 4, section 4.9

habitat, however, due to its close proximity to highly developed areas with high levels of human activities and busy roadways.

II.3.1.2 *Visual Environment*

The visual environment around TA–55 is that of an industrially developed site with a backdrop of forested and grass covered areas. Similarly, the larger industrial development within TA–3 is set against a predominately silvan backdrop. The surrounding TAs are either sparsely developed and forested, or their development is clustered into one or two areas with forested areas within their boundaries.

II.3.1.3 *Noise Environment*

Operations at TA–55 and TA–3 contribute to the overall background noise level generated by LANL activities, primarily through the traffic into and away from the facilities located within these TAs. Actual operational noise heard outside of structures is limited to the immediate vicinity of the buildings; mostly these noises are due to occasional routine maintenance activities (such as grass mowing) and the movement of equipment and waste containers into and around the facilities. No measurements of environmental noise have been conducted within the TA–55 area, but the level of noise present there and around the TA–3 area is fairly representative of other industrially developed sites around LANL.

II.3.2 Air Quality

Air monitors in the stacks at TA–55–4 and the CMR Building collect data from routine emissions. The index used in this SWEIS for the CMR Building radioactive stack emissions is 0.0002 curies per year (see Table 3.6.1–4 in chapter 3, volume I). The index for TA–55 radioactive stack emissions is 0.00002 curies per year of plutonium-239, and about 1,100 curies per year of tritium (in the form of hydrogen and water vapor) (see Table 3.6.1–2, chapter 3, in volume I).

II.3.3 Ecological Resources

II.3.3.1 *Threatened or Endangered Species*

DOE utilized existing available field information and a preliminary model of nesting and roosting habitat for the Mexican spotted owl to assess use of the TA–55 and TA–3 areas by species of animals and birds that are federally listed and state listed and protected as threatened or endangered. Three federally protected (also state listed) species of birds potentially use the areas for foraging habitat: the bald eagle (*Haliaeetus leucocephalus*), the American peregrine falcon (*Falco peregrinus*), and the Mexican spotted owl (*Strix occidentalis lucida*) (Haarmann 1997).

II.3.3.2 *Flora and Fauna*

The areas within the fenced portion of TA–55 where TA–55–4, the Brownfield Plutonium Facility, and the add-on to the TA–55–4 alternatives are proposed for location, are not available for use by any but the smallest wildlife species. This also is the case with the fenced portion of TA–3 around the CMR Building. These areas within the TA security fences are grassed over with a mixture of native and nonnative grass species and have small landscaped areas that include low lying bushes and a few small trees, but no large-trunked trees. The mesa-top area along the proposed transportation corridor within TA–55, TA–48, and TA–59 is predominantly covered with ponderosa pine (*Pinus ponderosa* Laws. *var. scoparium* Engelm.), with small stands of Gambel oak (*Quercus gambelii* Nutt.) understory trees (*Quercus gambelii*) and a groundcover of mostly mountain muhly grass (*Muhlenbergia montana* (Nutt. (A.S. Hitchc.) and blue grama grass (*Bouteloua gracilis* (H.B.K.) Lag.)). Wildlife in the mesa-top area includes a variety of insects, reptiles, birds, and mammals. Small mammals known to inhabit the area include voles (*Microtus* spp.), brush mice (*Peromyscus boylii*), and chipmunks (*Eutamias* spp.). Large mammals known to use and inhabit the area include game animals such as elk (*Cervus elaphus*) and mule deer (*Odocoileus hemionus*), as well as coyote (*Canis latrans*) and black bear (*Ursus americanus*). Field data suggest that many of these animals are attracted to and use surface water located in the upper portion of Mortandad Canyon to the northeast of TA–55.

II.3.4 Cultural Resources

Historic and archaeological sites are located in the vicinity of TA–55. These include a two-room pueblo (LA 12705) and historic wagon road (LA 71160) near the proposed corridor. LA 12705 has been determined eligible for the National Register of Historic Places (NRHP). LA 71160 has been determined ineligible for the NRHP (LANL 1996b). Other cultural properties are not expected to be found within the areas encompassed by the various alternatives because of the currently disturbed states of the potential alternative sites.

II.3.5 Traffic

Four publicly accessible vehicle routes convey traffic to and from LANL (Figure II.1.3–2). State Road 502 (Main Hill Road) and East Jemez Road are heavily used by commuter traffic from Santa Fe and Española. State Roads 4 and 501 (West Jemez Road) provide access to LANL for small communities to the west of LANL. Pajarito Road conveys traffic from White Rock to LANL. The four main portals to LANL convey about 40,000 average daily trips (ADTs). They are Los Alamos Canyon bridge (28,000 ADTs), Pajarito Road (8,000 ADTs), East Jemez Road (6,000 ADTs), and State Road 4 from the west (1,000 ADTs). East Jemez Road and Pajarito Road are DOE-owned and provide public access to many of the TAs at LANL.

In addition to private vehicles, government vehicles contribute to the volume of traffic on these roadways. Routine shipments of SNM are made across these roads in the DOE/U.S. Nuclear Regulatory Commission (NRC) Type B certified packaging. DOE has delegated the authority to LANL to temporarily close roads for the purpose of transporting hazardous or radioactive materials on DOE-owned roads. On average, the total number of on-site transfers of radioactive materials is approximately 950 per year. The number of hazardous or radioactive material shipments that actually require temporary road closures is approximately 80 per year. Road closures for on-site hazardous or radioactive material transfers are routinely conducted at one of three times: 5:00 a.m., 9:00 a.m., or 2:00 p.m. Road closures generally last less than 1 hour. Traffic is either held in place by security personnel or rerouted to the other available access roads at LANL. Because of the temporary and infrequent nature of the road closures and the ability to schedule road closures during off-peak hours, no discernible changes in routine traffic patterns are known to result from these actions at LANL.

II.3.6 Environmental Justice

Section 4.8, of chapter 4, volume I, discusses environmental justice and the populations near LANL. Because any of the alternative construction sites would have only local effects and the local populations are not minority or low-income populations, environmental justice considerations are complete in volume I, chapter 5.

II.3.7 Human Health

Work (including facility modification, maintenance and similar work) in the nuclear facilities at TA–55–4 and the CMR Building is presumed to involve exposure to radiation. Such work is conducted according to strict guidelines established by existing LANL standard operating procedures (SOPs). Under these SOPs, engineering and administrative controls are implemented to minimize worker and public exposure to radiation. Chapter 5 of volume I addresses projected worker doses at TA–55. Worker doses at the CMR Building are considerably lower than for TA–55.

Construction and relocation activities can expose workers to a variety of health risks and accidents, such as handling hazardous materials, being crushed beneath heavy equipment, back injuries, hidden electrical hazards, and working in a confined space. All work is performed according to SOPs for each type of task. In some cases, special work permits are required for work in secure areas or areas where radioactive or hazardous chemicals are present. Worker health is protected by the use of administrative controls and the wearing of personal protective equipment as needed and as specified in the special work permits.

II.3.8 Environmental Restoration and Waste Management

LANL has established procedures to be in compliance with all applicable laws and regulations for collecting, storing, treating, and disposing of waste. LANL's construction debris and nonhazardous solid waste are disposed of at the Los Alamos County Landfill on East Jemez Road. Typical radioactive wastes generated at TA–55 and the CMR Building include radioactive liquid waste, which is piped or trucked to the Radioactive Liquid Waste Treatment Facility (RLWTF) at TA–50; solid LLW, which is managed and may be disposed of at TA–54, Area G; and TRU waste, which is packaged and stored at TA–54 pending ultimate disposal at the Waste Isolation Pilot Plant (WIPP). In addition, mixed waste (containing both a radioactive and a *Resource Conservation and Recovery Act* (RCRA)-regulated hazardous component) is generated at these facilities. TRU mixed waste is transported to TA–54, Area

G, and stored there pending disposal at the WIPP. Solid, low-level mixed waste (LLMW)[4] and liquid LLMW are transported to TA–54, Area G, and TA–54, Area L, respectively, and stored there until appropriate disposal options become available. These options may include shipment off site to a commercial or other DOE facility for treatment and disposal.

The Environmental Restoration (ER) Project was established to identify the extent of environmental contamination at LANL from past practices and the appropriate means of cleaning it up under RCRA (as described in chapter 2, section 2.1.2). No potential release sites are known to exist in the immediate vicinity or are expected to be disturbed by activities planned under any of the alternatives under consideration in this PSSC analysis.

II.4 Environmental Consequences

Routine air emissions, wastewater, and solid waste projections from operations and their associated impacts are discussed in volume I (chapters 4 and 5) and are associated with the locations of facilities under the "CMR Building Use" Alternative. Impacts from the operations located in TA–55 could potentially be less than the TA–3 location; but, because routine emissions are so low, changes in impacts between these locations are not identifiable. Some aspects of impacts do not have a location difference. For example, radioactive wastewater treatment and radioactive waste disposal have the same final disposal locations under each alternative.

Impacts from operational accidents could show a locational difference because the CMR Building is closer to more members of the public than TA–55–4. The accident analysis section of volume I considers that the location for the operations requiring the additional space is in the CMR Building. Impacts due to accidents from these same operations being located in the vicinity of TA–55 could potentially be less. It is noted however, that this change would manifest only in the overall consideration of risk due to accidents. Existing operations with radioactive materials in the CMR Building and TA–55 represent the same potential hazards as those proposed for the future. The frequency of the potential accident might increase with an increase in the amount of work, but the potential consequences of such accidents have been considered for both facilities in chapter 5.

Another distinction among the alternatives is the creation of new nuclear space. The "CMR Building Use" Alternative is the only alternative that does not create any new nuclear space. Operations in new nuclear space under the other alternatives are assumed to create contaminated space and the liability for eventual decontamination and decommissioning. This is a conservative assumption and presents a bounding analysis for the alternatives presented in this PSSC analysis.

Note that any impacts associated with the dedicated transportation corridor would not be incurred at the 20 pits per year production rate.

II.4.1 Utilize Existing Unused Space in the CMR Building Alternative

II.4.1.1 *Land Use*

The expansion and reconfiguration activities to enhance plutonium pit manufacturing under this alternative would involve existing structures in TA–55–4 and the CMR Building at TA–3. Land uses in TA–55 and the CMR Building would not change from the current classification of use for research and development.

---

4. LLMW contains LLW, plus chemicals regulated as hazardous under the RCRA (42 United States Code [U.S.C.] §6901).

Under this alternative, a dedicated transportation corridor would be constructed to transport plutonium pits and various plutonium samples and components among the facilities at TA–55, the analytical chemistry operations at the CMR Building, and the nonnuclear support facilities in TA–3 (Figures II.2.1.1–1 and II.2.1.1–2). The corridor would be approximately 1 mile (1.6 kilometer) in length and 75 feet (23 meters) wide. It would occupy an area of approximately 7 acres (2.8 hectares). Development of the corridor would require road construction activities, including the removal of vegetation and the filling of a road bed. The dedicated corridor would cross Diamond Drive at its intersection with Sigma Road. At this intersection, a gate would be constructed to exclude public access during the movement of SNM into or out of the CMR Building. Public access to Pajarito Road would be allowed to continue unimpeded.

II.4.1.2 *Noise*

Implementation of the alternative to use existing CMR Building space would result in noise production both within the CMR Building and TA–55–4, as well as exterior to both structures in the case of the roadway and related construction actions. Noise produced from the construction activities conducted within both buildings and outside of structures would not likely affect the public. Involved workers would be exposed to levels of noise under normal working conditions, ranging from about 45 decibels A-weighted frequency scale (dBA) to 55 dBA for decontamination activities (May 1978) all the way up to slightly in excess of about 95 dBA for construction activities involving the use of heavy machinery (such as chainsaws, bulldozers, rock drills, and concrete mixers). At a distance of 50 feet (15 meters) from the work site, however, these noise levels would range from about 75 dBA to 95 dBA (Magrab 1975).

Most of the noise produced by the decontamination, construction, and reconfiguration activities at the CMR Building, TA–55, and the transportation corridor would fall below the occupational exposure limit (OEL) of the U.S. Occupational Safety and Health Administration (OSHA). Noise intensity would quickly decrease with distance from the source (Lipscomb and Taylor 1978). Any noise produced above 80 dBA would require the operators and nearby workers to participate in a personnel hearing conservation program (LANL 1993). The majority of the remodeling and construction activities would take place inside existing buildings, such as the CMR Building. The damping effect of building walls and greater than a 50-foot (15-meter) distance would reduce the noise levels below 80 dBA and to normal background levels (Canter 1996). The public would not be subjected to noise above 80 dBA at the closest public areas of Diamond Drive and Pajarito Road.

II.4.1.3 *Air Quality*

Radiological Emissions

Many proposed reconfiguration and associated activities would take place in the CMR Building. The decontamination and improvements would be conducted primarily indoors. The existing space to be remodeled would be physically segregated from the rest of the CMR Building. Normal operations would continue unhindered in the rest of the CMR Building. Engineering controls and SOPs would be in place to prevent radiological contaminants from leaving the work area. The room air would be filtered by the existing high-efficiency particulate air (HEPA) filters in the ventilation system during the reconfiguration. The CMR Building stack air exhaust would continue to be sampled. CMR Building improvements, such as installing a new heating, ventilation, and air conditioning (HVAC) system would be made only after appropriate decontamination procedures were followed.

Workers would wear appropriate protective gear and radiation dosimetry for performing decontamination. The applicable SOPs for decontaminating interior spaces and equipment would be followed. Radiological monitoring of the workers and work space would be conducted routinely to assure containment of any radioactive contamination. Under these administrative, engineering controlled, and closed systems, no radioactive material would be expected to be released into the environment. The radiological air quality outside the CMR Building would not be expected to vary from normal operations. The workers and public would not be affected, with respect to radiological air emissions, from these decontamination and improvement activities at the CMR Building because any contaminated air would be filtered before leaving the building. Any radioactive waste from the decontamination process would be transported to TA–54, Area G following the current SOPs, which call for closing public access to Diamond Drive and Pajarito Road during radioactive waste transport. The public would not be affected because of the road closure.

The construction of a new transportation corridor between TA–55 and the CMR Building at TA–3 would be along Mortandad Canyon and Pajarito Road. The stretch of land is comprised of developed areas and forest. No solid waste management units (SWMUs) or radioactively contaminated soils are present along the corridor route (LANL 1990). The ground leveling, road paving, and construction of guard stations and security fences would not contribute additional radioactive air emissions from the area. No facilities or operations exist along the corridor that would emit radioactive constituents to the atmosphere. The radiological air quality of this area would not be expected to change from the historical average for the area. No environmental impacts with respect to radiological air emissions would be expected for workers or the public from the construction of the transportation corridor.

Nonradiological Emissions

The air emissions of nitrogen oxides, carbon monoxide, sulfur oxides, and particulate matter from construction equipment exhaust only occur during the periods of active construction and are small compared to routine vehicle emissions associated with traffic in the area. Workers and the public would not be impacted by these emissions primarily because of the low volume of emissions and distance from the construction sites to the nearest public area.

II.4.1.4 *Ecological Resources*

Threatened or Endangered Species

Bald Eagle. LANL studies indicate that the bald eagle may occasionally forage in the areas proposed for the transportation corridor under the “CMR Building Use” Alternative. The bald eagle primarily occurs in habitats along permanent streams, rivers, and lakes. The areas proposed for use in the “CMR Building Use” Alternative do not contain permanent streams, rivers, or lakes. Therefore, these areas are considered only low-level use foraging habitat for the bald eagle. The loss of this small amount of low-level use foraging habitat would not have any appreciable effect on this species.

Peregrine Falcon. LANL studies indicate that the areas proposed for the transportation corridor constitute less than 0.05 percent of the total area available for potential foraging habitat for the peregrine falcon within the LANL boundary. Because this represents only a small portion of the total foraging habitat for the peregrine falcon, this would not have any appreciable effect on this species.

Mexican Spotted Owl. The area proposed for the transportation corridor has been analyzed using the preliminary model for Mexican spotted owl potential nesting and roosting habitat. The results of the analysis indicated that fragmented patches of potential nesting/ roosting habitat exist within 0.2 mile (322 meters) of the proposed corridor. This area is already considerably disturbed by noise and light from existing roads and buildings near the site. Given the fragmented nature of this potential habitat and the current level of disturbance, the "CMR Building Use" Alternative should not contribute additional disturbances to the potential habitats. The preliminary model also indicated that the corridor includes Mexican spotted owl foraging habitat. It is estimated that the loss of foraging habitat to the owl would represent roughly 0.06 percent of the total available foraging habitat within the LANL boundary. The loss of this foraging habitat would not have any appreciable effect on this species.

Flora and Fauna

The upgrades for the "CMR Building Use" Alternative are primarily indoor upgrades to existing facilities, with the exception of the transportation corridor. The transportation corridor could contain a security fence that would alter approximately 1 mile (1.6 kilometers) of large mammal and predator movement along Pajarito Road in the vicinity of TA–59 and TA–48, but would not restrict game animal movement within the immediate vicinity. The removal of about 7 acres (2.8 hectares) of overstory and understory vegetation within the proposed road corridor would displace small mammals and birds.

II.4.1.5 *Cultural Resources*

No adverse effects to cultural resources are expected to occur under this alternative. The NRHP-eligible site along the transportation corridor would be avoided, if possible. If the site cannot be avoided, appropriate mitigation measures, including data recovery, would be designed and implemented in consultation with the New Mexico State Historic Preservation Office(r) (SHPO) (LANL 1996b).

II.4.1.6 *Traffic*

This alternative is expected to increase the volume of traffic at the CMR Building on Diamond Drive and at TA–55 on Pajarito Road during the construction of facilities and operations that support enhanced pit manufacturing at LANL. Vehicles required to transport construction workers' materials would contribute to an increase in local traffic. This additional traffic load is anticipated to occur primarily within the first 3 years of the project. Pajarito Road currently averages about 8,000 vehicle trips per day and Diamond Drive about 13,000 vehicle trips per day. Assuming an additional 600 vehicle trips per day due to construction and a fairly even distribution to both roads, increases are projected to be about 2 to 5 percent. Effects of this increase would not be significant. Construction activities at TA–55 would not require the permanent or extended closure of any public roads or rerouting of traffic. Temporary closures could be required to accommodate certain construction activities.

Construction activities could temporarily decrease the number of available employee parking spaces and interfere with the existing employee parking situation in TA–3 and TA–55. Construction activities could adversely affect the traffic flow around TA–55 primarily at the start and end of each work day. At a minimum, the potential shortage of parking spaces would result in delays for both site workers and construction workers and could result in an increase in the number of vehicular accidents. Following completion of construction activities, sufficient parking would be available.

During peak operations, up to an additional 140 employees are anticipated to be on the site. Assuming 280 vehicle trips as a result, an increase of about 1 to 2 percent in traffic is projected for Diamond Drive and Pajarito Road. With the related construction traffic no longer present, the effect of this traffic increase would not be significant.

The construction and operation of a dedicated transportation corridor between TA–55 and TA–3 is proposed as part of this alternative. It would restrict vehicular access to TA–48, the Sigma Complex in TA–3, and public use of Diamond Drive because it would cross the access roads into each of these TAs and Diamond Drive. The construction and operation of railroad-type crossing gates at the intersection of Diamond Drive and Sigma Road and at the entrance of TA–48 off of Pajarito Road would restrict traffic movements during construction and would stop traffic when dedicated vehicles are using the corridor. Based on an estimated peak rate of 500 SNM shipments each year using the corridor and 220 working days per year, the number of road closures would average less than three per working day and last less than 15 minutes per closure. These closures would be coordinated to avoid peak traffic hours. No members of the public would be allowed access to the dedicated transportation corridor.

The use and operation of the transportation corridor would reduce the number of LANL vehicles that carry SNM on publicly accessible Pajarito Road and Diamond Drive by approximately 500 shipments per year or about three vehicles per work day. This decrease in traffic volume would result in a reduction in the potential for vehicular accidents involving SNM. However, radioactive materials from other LANL operations would continue to use publicly accessible roads. The dedicated transportation corridor also would provide for incremental improvements in the level of security and efficiency in transporting SNM between TA–55 and the CMR Building.

II.4.1.7 *Human Health*

Human health impacts may potentially result from decontamination of equipment, relocation of equipment and materials, and the construction and interior modifications that would be performed over the transition period. Radiological impacts may result from exposure to plutonium, uranium, tritium, and a variety of actinides when these materials are moved to new locations and as workers reconfigure radiological control areas.

Workers involved in construction of a new guard gate and the construction of a safe and secure transportation corridor would not be exposed to radioactivity at levels above background. Doses to construction workers are expected to be no higher than doses to permanent LANL workers. LANL worker doses are displayed in Table II.4.1.7–1 and discussed below.

Workers involved in decontamination and building modification activities at TA–55 and the CMR Building would be working in radiological control areas and in areas adjacent to ongoing operations, and therefore, would have a greater exposure to radioactivity than the workers mentioned in the preceding paragraph. Approximately 364,000 labor hours would be needed to accomplish the decontamination and reconfiguration activities within TA–55–4. In order to estimate potential health effects, the external dose to construction workers at TA–55 is assumed to be approximately the same as that received by radiological control technicians and by Johnson Controls, Inc. (JCI), workers performing routine maintenance and equipment installations at TA–55–4. As a group, these technicians and workers received about 0.12 millirem per hour. Therefore, the collective dose to workers performing the decontamination and building modifications is estimated to be about 45 person-rem. Using a risk conversion factor of 4×10^{-4} excess latent cancer fatality (LCF) per person-rem

TABLE II.4.1.7–1.—*Radiological Doses and Excess Latent Cancer Fatalities for Construction Activities Under the "CMR Building Use" Alternative*

WORKERS	HISTORICAL COLLECTIVE DOSE RATE (rem/hr)	EXPOSURE LENGTH (person-hours)	COLLECTIVE DOSE (person-rem)	EXCESS LATENT CANCER FATALITIES
Construction Worker at TA–55	0.00012[a]	364,000	43.68	0.018
Construction Worker at CMR Building	0.0000039[b]	305,000	1.19	0.00048

[a] Stokes 1997
[b] PC 1996

(International Commission on Radiological Protection [ICRP] 1991), this means that 1.8 x 10^{-2} excess LCF would be expected over the life of the "CMR Building Use" Alternative. In other words, it is unlikely that the decontamination and building modifications would result in any excess cancer fatalities among the construction worker population.

Approximately 305,000 labor hours would be needed to accomplish the decontamination and reconfiguration activities within the CMR Building. The external dose to construction workers at the CMR Building is assumed to be approximately the same as that received by radiological control technicians and by JCI workers performing routine maintenance and equipment installations at the CMR Building. Based on a review of their radiation exposures, these technicians and workers received on average about 0.0039 millirem per hour. Therefore, the collective dose to workers performing the decontamination and building modifications is estimated to be 1.2 person-rem. Using a risk conversion factor of 4 x 10^{-4} excess LCF per person-rem, this means that 4.8 x 10^{-4} excess LCF would be expected over the life of the "CMR Building Use" Alternative. In other words, it is highly unlikely that the decontamination and building modifications would result in any excess cancer fatalities among the worker population.

Worker exposures to radiation and radioactive materials in radiological control areas would be controlled under established procedures that require doses to be kept as low as reasonably achievable. Any potential hazards would be evaluated as part of the radiation worker and occupational safety programs at LANL. Nonroutine construction activities may require special work permits with worker protection measures given for specific locations and activities. Under the "CMR Building Use" Alternative, the public would not receive any additional radiological dose beyond the background level. Therefore, no adverse human health effects to the public are anticipated.

II.4.1.8 *Waste Management*

The "CMR Building Use" Alternative would produce waste from the construction of a new dedicated transportation corridor, interior building modifications, and the replacement of old equipment used to support pit manufacturing operations in TA–55–4 and the CMR Building. The types of waste that could be generated from these activities would include nonhazardous solid waste from construction activities, RCRA waste, *Toxic Substances Control Act* (TSCA) (15 U.S.C. §2601) polychlorinated biphenyl (PCB) waste, LLW, and LLMW from modifications to manufacturing operations. Sanitary wastes also would be generated from the construction activities. Table II.4.1.8–1 shows the estimated volumes of radioactive waste that would be generated from the construction activities. As shown in Table II.4.1.8–1, the total volume of radioactive waste that would be generated by construction and building modifications would be 2,685 cubic yards (77 cubic meters) over the 3 to 4 years of construction activity.

Nonhazardous wastes would be disposed of in the Los Alamos County Landfill, which has adequate capacity to handle the projected amount of waste. RCRA and PCB wastes would be sent off site for treatment and disposal at a commercial facility. Commercial treatment is readily available and currently used to treat most LANL RCRA wastes. LLW would be taken to TA–54, Area G or to a permitted off-site facility for disposal. LLMW would be stored at Area G pending the selection of an acceptable treatment and disposal option. Because of the relatively small amount of LLW and LLMW that would be produced, the "CMR Building Use" Alternative is not expected to adversely affect the disposal or storage capacity at Area G. Sanitary wastes could either be collected by subcontractors during construction operations or be put into the LANL sanitary sewer system. The anticipated volume of sanitary wastes would not be expected to have any effect on the existing capacity of the sanitary sewer system.

II.4.2 Brownfield Plutonium Facility Alternative

II.4.2.1 *Land Use*

The proposed activities would be conducted within areas that are already heavily disturbed for industrial use connected to research and development purposes. The new structure proposed under this alternative would be built within the fenced area of TA–55 that has already undergone heavy disturbance and clearing for security reasons related to TA–55–4. Implementation of the Brownfield Alternative would not result in a change to the land use classification currently assigned to TA–55.

As discussed in section II.4.1.1, under this alternative, a dedicated transportation corridor would be constructed to transport plutonium pits and various plutonium samples and components among the facilities at TA–55, the analytical chemistry operations at the CMR Building, and the nonnuclear support facilities in TA–3.

II.4.2.2 *Noise*

Implementation of the Brownfield Alternative would result in actions that create noise, both within TA–55–4 and outside the building. Noise produced from the construction activities conducted within TA–55–4 and outside the

TABLE II.4.1.8–1.—*Total Radioactive Waste Generation from Construction Under the "CMR Building Use" Alternative*[a]

WASTE TYPE	TA–55, PF–4 (yd^3/m^3)	CMR BUILDING (yd^3/m^3)	TA–55 PLUS CMR (yd^3/m^3)
TRU	300/229	258/197	558/426
TRU Mixed	—	377/288	377/288
LLW	300/229	1,410/1,077	1,710/1,306
LLMW	—	40/31	40/31
Total Waste	600/458	2,085/1,593	2,685/2,051

PF = Plutonium Facility, yd = yards, m = meters
[a] Time period is the entire period of construction, 3 to 4 years.

structure would not likely affect the public. Involved workers would be exposed to levels of noise under normal working conditions, ranging from about 45 dBA to 55 dBA for decontamination activities (May 1978), all the way up to slightly in excess of about 95 dBA for construction activities involving the use of heavy machinery (such as chainsaws, bulldozers, rock drills, and concrete mixers). At a distance of 50 feet (15 meters) from the work site, however, these noise levels would range from about 75 dBA to 95 dBA (Magrab 1975).

Most of the noise produced by the construction activities at TA–55 would fall below dBA OEL of the OSHA. The high-level noise generated would be localized at the work sites. Any noise produced above 80 dBA would require the operators and nearby workers to participate in a personnel hearing conservation program as per LANL administrative requirements. The public would not be subjected to noise above 80 dBA at the closest public areas of Diamond Drive and Pajarito Road.

Under this alternative, TA–55 workers not involved in the construction activity would not be subjected to excessive noise produced by construction activities because they are physically removed from the construction site. The public would not be affected by the construction- and improvement-generated noise, also due to the distance from the construction activities to the public.

II.4.2.3 *Air Quality*

Radiological Emissions

The construction of a new building at TA–55 would take place within the current boundary for the TA. The vacant ground within the TA–55 secured area has been previously disturbed but is not contaminated. The construction of a new building would not contribute additional radioactive air emissions above normal operations for TA–55. The radiological air quality would not be expected to change from the historical average for the area. Workers and the public at or along Pajarito Road would not be impacted by radiological air emissions because no such emissions would be generated by the construction.

Nonradiological Emissions

The air emissions of nitrogen oxides, carbon monoxide, sulfur oxides, and particulate matter from construction equipment exhaust only occur during the periods of active construction and are small compared to routine vehicle emissions associated with traffic in the area. Impacts to workers would be minimal because the emissions are of relatively low volume. The public would not be impacted for this reason as well because of the distance from the construction site to the public.

II.4.2.4 *Ecological Resources*

Threatened or Endangered Species

The construction of a Brownfield Plutonium Facility in a previously disturbed area near the TA–55 Plutonium Facility would result in the loss of less than 0.01 percent of the total LANL foraging habitat for the bald eagle, peregrine falcon, and Mexican spotted owl. Less than 0.05 percent of these species habitats would be affected by the proposed transportation corridor. This would not result in an appreciable effect on these species.

II.4.2.5 *Cultural Resources*

No adverse effects to cultural resources from construction of a new stand-alone facility within the current security fence at TA–55 are expected to occur under this alternative. If the facility were to be sited elsewhere at TA–55, cultural resources surveys would not likely be required to determine the effect of construction because of the disturbed nature of TA–55. As discussed in section II.4.1.5, the NRHP-eligible site located along the transportation corridor would not be disturbed in order to avoid having an impact on the site.

II.4.2.6 *Traffic*

This alternative is expected to increase the volume of traffic at nearby TA–55 during the construction of facilities and operations that support pit manufacturing at LANL. Vehicles required to transport construction materials and workers would contribute to an increase in local traffic. This additional traffic load is anticipated to occur primarily within the first 3 years of the anticipated 4-year project. Based on an average daily traffic rate of approximately 8,000 vehicle trips per day on Pajarito Road and assuming an additional 600 construction vehicle trips per day, the increase in vehicle traffic from construction activities is estimated to be no more than about 8 percent above routine traffic volumes. Effects of this increase would not be significant. Construction activities at TA–55 would not require the permanent or extended closure of any public roads or rerouting of traffic. Temporary closures of short duration could be required to accommodate certain construction activities.

Construction activities could decrease the number of available employee parking spaces and interfere with the existing employee parking situation in the area. The construction of new facilities near TA–55 could result in additional temporary loss of parking spaces if construction equipment and trailers are located in existing parking areas. Construction activities could adversely affect the traffic flow around TA–55, primarily at the start and end of each work day. At a minimum, the potential shortage of parking spaces would result in delays for both site workers and construction workers and could result in an increase in the number of vehicular accidents. Following completion of construction activities, sufficient parking would be provided for all workers at TA–55. Impacts from the construction of the dedicated transportation corridor would be the same under this alternative as under the Preferred Alternative.

During peak operations, up to an additional 140 employees are anticipated to be on the site. Assuming 280 vehicle trips per day as a result, an increase of about 3 percent in traffic is projected for Pajarito Road. With the related construction traffic no longer present, the effect of this traffic increase would not be significant.

II.4.2.7 *Human Health*

Human health impacts may potentially result from the construction of a Brownfield Plutonium Facility. Radiological impacts may result from exposure to plutonium, uranium, tritium, and a variety of actinides when these materials are moved to the new facility location. Workers involved in construction activities at TA–55 would not be exposed to radioactivity at levels above background. Workers involved in building modification activities at TA–55 would be working in radiological control areas and in areas adjacent to ongoing operations. Worker exposures to radiation and radioactive materials in radiological control areas would be controlled under established procedures that require doses to be kept as low as reasonably achievable. Any potential hazards would be evaluated as part of the radiation worker and occupational safety programs at LANL. Nonroutine construction activities may require special work permits with worker protection measures given for specific locations and activities. Doses to construction workers would be expected to be equal to or less than those received by workers under the "CMR Building Use" Alternative (Table II.4.1.7–1). Under this alternative, the public would not receive any additional radiological dose beyond the background level. Therefore, no adverse human health effects to the public are anticipated.

II.4.2.8 *Waste Management*

This alternative would produce waste from the construction of a new building at TA–55 that would include 15,300 square feet (1,425 square meters) of designated nuclear material laboratory space. The types of waste that could be generated from this activity would include nonhazardous solid waste from construction activities and possibly RCRA waste. Sanitary wastes also would be generated under this alternative. Small amounts of LLW could be generated in the process of relocating equipment to the new facility (this waste would have to be treated and disposed). The total volume of RCRA wastes also would be minimal. Nonhazardous wastes would be disposed of in the Los Alamos County Landfill, which has adequate capacity to handle the projected amount of waste. RCRA wastes would be sent off site for treatment and disposal at a commercial facility. Commercial treatment is readily available and currently used to treat most LANL RCRA wastes. Sanitary wastes could either be collected by subcontractors during construction operations or be put into the LANL sanitary sewer system. The anticipated volume of sanitary wastes would not be expected to have any effect on the existing capacity of the sanitary sewer system. This alternative also would create new nuclear space at LANL, which would imply a liability for future cleanup (and related waste generation).

II.4.3 Add-On to TA–55–4 Alternative

II.4.3.1 *Land Use*

The proposed activities would be conducted within areas that are already used for research and development purposes. Implementation of this alternative would not change the land use designations of TA–55 or adjacent areas.

As discussed in section II.4.1.1, under this alternative, a dedicated transportation corridor would be constructed to transport plutonium pits and various plutonium samples and components among the facilities at TA–55, the analytical chemistry operations at the CMR Building, and the nonnuclear support facilities in TA–3.

II.4.3.2 *Noise*

Implementation of the Add-on to TA–55–4 Alternative would result in actions that create noise, both within TA–55–4 and outside the building. Noise produced from the construction activities conducted within the TA–55–4 building and outside the structure would not likely affect the public. Involved workers would be exposed to levels of noise under normal working conditions ranging from about 45 dBA to 55 dBA for decontamination activities (May 1978) all the way up to slightly in excess of about 95 dBA for construction activities involving heavy machinery (such as chainsaws, bulldozers, rock drills, and concrete mixers). At a distance of 50 feet (15 meters) from the work site, however, these noise levels would range from about 75 dBA to 95 dBA (Magrab 1975).

Most of the noise produced by the construction activities at TA–55 would be below the OEL of OSHA. The noise generated would be confined to TA–55 and to the new transportation corridor. The high-level noise generated would be localized at the work sites. Any noise produced above 80 dBA would require the operators to participate in a personnel hearing conservation program as per LANL administrative requirements. The public at Pajarito Road would not be affected by the noise levels because the noise would fall below 80 dBA after 50 feet (15 meters) from the work site.

II.4.3.3 *Air Quality*

Radiological Emissions

The construction of a new add-on facility at TA–55–4 would take place within the current security boundary of the area. The vacant ground within the TA–55 secured area has been previously disturbed, but is not contaminated. No SWMUs or radioactively contaminated soils are present within the vacant area (LANL 1990). The construction, erection, and finishing of the add-on facility would not contribute additional radioactive air emissions above normal operations for TA–55. The radiological air quality would not be expected to change from the historical average for the area. Workers and the public would not be affected by the building construction.

Nonradiological Emissions

The air emissions of nitrogen oxides, carbon monoxide, sulfur oxides, and particulate matter from construction equipment exhaust only occur during the periods of active construction and are small compared to routine vehicle emissions associated with traffic in the area. Workers and the public would not be impacted by these emissions primarily because of the low volume of emissions and distance from the construction sites to the nearest public area.

II.4.3.4 *Ecological Resources*

Threatened or Endangered Species

Under this alternative, there would be negligible (less than 0.06 percent) loss of bald eagle, peregrine falcon, and Mexican spotted owl foraging habitat. This would not result in any appreciable effect on these species.

II.4.3.5 *Cultural Resources*

No adverse effects to cultural resources from construction of an addition to TA–55–4 within the current security fence are expected to occur under this alternative. As discussed in section II.4.1.5, the NRHP-eligible site along the transportation corridor would be avoided during construction of the corridor.

II.4.3.6 *Traffic*

Traffic patterns and volumes required to support new construction or the reconfiguration of existing facilities under this alternative would be increased at TA–55. Based on an average daily traffic rate of approximately 8,000 ADTs on Pajarito Road and assuming an additional 600 construction vehicle trips per day, the increase in vehicle traffic from construction activities is estimated to be no more than about 8 percent above routine traffic volumes. Effects of this increase would not be significant. Construction activities at TA–55 would not require the permanent or extended closure of any public roads or rerouting of traffic. Temporary closures of short duration could be required to accommodate certain construction activities.

Construction activities could decrease the number of available employee parking spaces and interfere with the existing employee parking situation in the area. The construction of new facilities at TA–55 could result in additional temporary loss of parking spaces if construction equipment and trailers are located in existing parking areas. Construction activities could adversely affect the traffic flow around TA–55 primarily at the start and end of each work day. At a minimum, the potential shortage of parking spaces would result in delays for both site workers and construction workers and could result in an increase in the number of vehicular accidents. Following completion of construction activities, sufficient parking would be provided for all workers at TA–55. Impacts from the construction of the dedicated transportation corridor would be the same under this alternative as under the Preferred Alternative.

During peak operations, up to an additional 140 employees are anticipated to be on the site. Assuming 280 vehicle trips as a result, an increase of about 3 percent in traffic is projected for Pajarito Road. With the related construction traffic no longer present, the effect of this traffic increase would not be significant.

II.4.3.7 *Human Health*

Workers involved in the construction of the add-on facility at TA–55–4 could be exposed to plutonium, uranium, tritium, and a variety of actinides when these materials are moved to new locations and as workers reconfigure existing radiological control areas. Some reconfiguration and remodeling work would be performed inside TA–55–4. Workers performing these activities are expected to receive about the same doses as workers performing the "CMR Building Use" Alternative. Doses to construction workers would be expected to be equal to or less than those received by workers under the "CMR Building Use" Alternative (Table II.4.1.7–1). Under this alternative, the public would not receive any additional radiological dose beyond the background level. Therefore, no adverse human health effects are anticipated under this alternative.

II.4.3.8 *Waste Management*

This alternative would produce waste from the construction of an add-on building at TA–55 that would include approximately 15,300 square feet (1,425 square meters) of laboratory space. The types of waste that could be generated from these activities would include nonhazardous solid waste from construction activities and possibly RCRA waste. Sanitary wastes would also be generated under this alternative. Some LLW could be generated in the process of relocating equipment to the new space. The total volume of nonhazardous waste and the amount of RCRA waste would be minimal. Nonhazardous wastes would be disposed of in the Los Alamos County Landfill, which has adequate capacity to handle the projected amount of waste. RCRA wastes would be sent off site for treatment and disposal at a commercial facility. Commercial treatment is readily available and currently used to treat most LANL RCRA wastes. Sanitary wastes could either be collected by subcontractors during construction operations or be put into the LANL sanitary sewer system. The anticipated volume of sanitary wastes would not be expected to have any effect on the existing capacity of the sanitary sewer system. This alternative also would create new nuclear space at LANL, which would imply a liability for future cleanup (and related waste generation).

II.4.4 Comparison of Alternatives

Table II.4.4–1 shows a summary of the potential impacts of the alternatives.

There are few differences in the construction impacts across the PSSC alternatives. Because all of the construction (except for the proposed transportation corridor) would occur within previously disturbed areas and would result in land use consistent with the existing use of land in these areas, no land use, cultural resource, or ecological resource impacts would be anticipated unless the proposed transportation corridor were constructed. Construction of this corridor under any of the alternatives would have an equal impact under any of the alternatives; but the land use, ecological resources, and cultural resources impacts of constructing the corridor would be minimal. Construction noise and construction traffic impacts would be minimal under any of the alternatives with or without the transportation corridor. If the corridor is constructed, it would mitigate operational impacts by substantially reducing the operational transport on public roads under the Expanded Operations Alternative. (This is true under all of the PSSC alternatives, but this mitigation is more important for the "CMR Building Use"

TABLE II.4.4–1.—*Summary of Potential Impacts of the Alternatives*

FACTOR, MEASURE	"CMR BUILDING USE" ALTERNATIVE[a]	BROWNFIELD ALTERNATIVE	ADD-ON TO TA–55–4 ALTERNATIVE
Land Use	No change in land use designations of research and development for TA–55 and TA–3. Development of the transportation corridor would change disturbed but undeveloped land to industrial land use.	No change in land use designations of research and development for TA–55 and TA–3. Development of the transportation corridor would change disturbed but undeveloped land to industrial land use.	No change in land use designations of research and development for TA–55 and TA–3. Development of the transportation corridor would change disturbed but undeveloped land to industrial land use.
Noise	Increased noise levels temporarily to 80 dBA and above for TA–3 and TA–55 construction workers. Noise levels not likely to affect the public.	Increased noise levels temporarily to 80 dBA and above for TA–55 construction workers. Noise levels not likely to affect the public.	Increased noise levels temporarily to 80 dBA and above for TA–55 construction workers. Noise levels not likely to affect the public.
Air Quality	Minor radiological emissions during construction phase. Nonradiological emissions expected during construction period.	No radiological emissions during construction phase. Nonradiological emissions expected during construction period.	No radiological emissions during construction phase. Nonradiological emissions expected during construction period.
Ecological Resources	Loss of < 0.1 percent of foraging habitat for individual threatened or endangered species due to the construction of the optional dedicated road; no appreciable effect to individual threatened or endangered (T&E) species.	Loss of < 0.05 percent of foraging habitat for individual threatened or endangered species due to the construction of the optional dedicated road; no appreciable effect to individual T&E species.	Loss of < 0.05 percent of foraging habitat for individual threatened or endangered species due to the construction of the optional dedicated road; no appreciable effect to individual T&E species.
Cultural Resources	No disturbance of archeological sites.	No disturbance of archeological sites.	No disturbance of archeological sites.
Traffic	Vehicular traffic on Pajarito Road, Diamond Drive, and West Jemez Road would increase by 5 percent or less during construction phase. Transport of SNM would increase.	Vehicular traffic on Pajarito Road would increase by about 8 percent during construction phase. Transport of SNM would increase.	Vehicular traffic on Pajarito Road would increase by about 8 percent during construction phase. Transport of SNM would increase.
Human Health	Potential physical and construction related hazards. Minimal worker radiation hazard (0.018 excess LCFs); no radiation risk to the public.	Potential physical and construction related hazards. Minimal worker radiation hazard (0.018 excess LCFs); no radiation risk to the public.	Potential physical and construction related hazards. Minimal worker radiation hazard (0.018 excess LCFs); no radiation risk to the public.

TABLE II.4.4–1.—*Summary of Potential Impacts of the Alternatives*-Continued

FACTOR, MEASURE	"CMR BUILDING USE" ALTERNATIVE[a]	BROWNFIELD ALTERNATIVE	ADD-ON TO TA–55–4 ALTERNATIVE
Waste Management	LLW disposed of at LANL disposal site or off site. Nonhazardous wastes disposed of at county landfill. RCRA and PCB waste disposed of at off-site commercial facility.	Nonhazardous wastes disposed of at county landfill. Any RCRA waste would be disposed of at off-site commercial facility. Creates additional nuclear space, which would constitute a future cleanup liability.	Nonhazardous wastes disposed of at county landfill. Any RCRA waste would be disposed of at off-site commercial facility. Creates additional nuclear space, which would constitute a future cleanup liability.
Accidents	Unlikely to occur with worker and public dose; accident would result in off-site maximally exposed individual (MEI) dose of about 8 rem (resulting in 0.005 excess LCFs). The worker involved would inhale plutonium; this would not result in an acute worker fatality, but would result in an incremental risk of death from cancer over the worker's lifetime. (Risk is dependent on several factors and cannot be quantified.)	Unlikely to occur with worker and public dose; accident would result in off-site MEI dose of about 8 rem (resulting in 0.005 excess LCFs). (Risk is dependent on several factors and cannot be quantified.)

[a] Utilize existing unused space in the CMR Building.

Alternative because it would result in the greatest operational transport between TA–55 and the CMR Building out of the three PSSC alternatives.)

The few differences in construction impacts across the PSSC alternatives are attributable to the difference between construction within an existing nuclear facility and construction to create additional nuclear facility space. Air emissions for construction within existing nuclear space (as proposed under the "CMR Building Use" Alternative) would include radiological emissions because of the radioactive material contamination (primarily in equipment) in the areas involved in the construction, in addition to the nonradioactive emissions from construction equipment exhaust. The creation of new nuclear facility space would not result in radioactive air emissions and would have comparable nonradioactive emissions from construction equipment exhaust. Similarly, construction under the "CMR Building Use" Alternative would result in construction workers receiving radiation doses due to the ongoing nuclear operations in the areas of the facility that are not involved in the construction activities, and the construction waste generated from within the existing facilities would include some LLW and TRU waste for disposal. These impacts would not be expected under the Brownfield or Add-on to TA–55–4 Alternatives (except for the relatively small exposures and waste quantities generated in moving existing contaminated equipment into the new facilities). Finally, the "CMR Building Use" Alternative utilizes existing nuclear space, which does not incur a new liability for cleanup of contaminated space. (The areas used under this alternative are presumed to be contaminated from past activities in these areas.) The Brownfield or Add-on to TA–55–4 Alternatives would result in the construction of about 15,000 square feet (about 1,400 square meters) of new nuclear space, which implies a liability for future cleanup and related radioactive waste generation.

II.5 POTENTIAL ACCIDENT SCENARIO

One additional accident with significant consequences was analyzed for the "CMR Building Use" Alternative. This accident involved construction activities only. Operational and transportation accidents are addressed in chapter 5 of volume I. The construction accident scenario was developed to evaluate potential impacts on the workers and the public in and around TA–55 and the dedicated transportation corridor development areas. The details of the accident analysis are described in the following text and, in more detail, in appendix II.B.

II.5.1 Construction Accident

This hypothetical accident scenario was developed for the TA–55 Safety Analysis Report (LANL 1996a) to evaluate the impact to individuals at a construction site. Construction workers and their management would be located in and around the TA–55 area where building modifications would be made in support of the enhanced pit manufacturing operations. Heavy equipment would be located and operated on site. During normal conditions, laboring construction workers and operating machinery would be present at the site.

The postulated accident would occur during the reconfiguration of a building. This scenario is based on a postulated accident during modifications or upgrades of structures, systems, or components at TA–55–4. The scenario is initiated by the accidental drop of a plutonium dioxide storage container during movement to or from storage in order to perform a building modification or upgrade activity. The container is assumed to rupture upon impact with the floor, resulting in an airborne release of particulate matter. A worker is exposed. The suspended particulate matter is processed through the ventilation system and released through the north exhaust stack, assuming that the ventilation system and HEPA filtration are not operable. (See appendix II.B for a discussion of this accident assuming these systems remain operable.)

An accident of this type would have an occurrence frequency that makes it an unlikely event (appendix II.B) under any of the SWEIS alternatives. “Unlikely” is defined as a frequency between 1 in 100 years and 1 in 10,000 years or at least once in 10,000 similar facilities operated for 1 year. Under this postulated accident, the worker who dropped the container would be exposed to a significant inhalation dose, but no acute worker fatality occurs. The risk to this worker is highly dependent on the type of protective measures taken at the time of the accident, the speed with which these measures are taken, and the effectiveness of medical treatment after exposure; as such, the risk to this worker cannot be predicted quantitatively or reliably. The dose to the off-site maximally exposed individual (MEI) is 8.1 rem, which corresponds to a risk of about 0.005 excess LCFs.

APPENDIX II.A CAPABILITIES AND FLOORSPACE REQUIREMENTS UNDER THE EXPANDED OPERATIONS ALTERNATIVE

This appendix provides more information about the TA–55–4 nuclear materials capabilities and their floorspace requirements to supplement the discussion in section II.1.4.

II.A.1 Manufacturing of Plutonium Components

Existing capabilities for pit manufacturing at LANL have developed and maintained the technology base required to build research and development pits and pits that can replace individual units removed from the stockpile for surveillance and other purposes. Current floorspace allocation for this capability, which includes general pit manufacture, disassembly, and assembly is 11,400 square feet (1,060 square meters). Based on the SSM PEIS (DOE 1996) and its ROD (61 FR 68014), DOE has chosen to meet its future pit production needs by expanding this existing manufacturing capability. With this expansion, DOE would be able to produce up to 50 pits per year (single shift) and 80 pits per year with multiple shifts. Floorspace allocation for this expanded capability is 15,300 square feet (1,425 square meters) of contiguous space in TA–55–4 and 3,200 square feet (298 square meters) for the additional space addressed in this PSSC analysis. This 3,200 square feet (298 square meters) would be used primarily to test new technologies outside of the production lines and to prepare components for testing.

II.A.2 Disassembly and Surveillance of Weapons Components

LANL conducts destructive and nondestructive evaluations on pits to evaluate stockpile reliability and staging safety. These pits also are disassembled, and the plutonium contained therein is converted to oxide for storage or other uses. Each destructive evaluation, depending on pit type, includes the following operations: leak testing, weighing, dimensional inspection, dye penetrant inspection, radiography, metallography, chemical analysis, and microtensile testing. Most of these disassembly and surveillance activities are performed at TA–55–4 and share equipment with pit manufacturing operations. Approximately 20 pits are examined each year. The disassembly capacity is greater than this, and is at times used to disassemble additional pits. The pit material remaining after the evaluation is stored in the TA–55–4 vault. These functions are candidates for transfer from TA–55–4 to the additional space addressed in this PSSC analysis. If transferred, these activities would no longer be able to use the pit manufacturing equipment at TA–55–4 (thus, additional equipment and floorspace would be required).

Under the Expanded Operations Alternative, LANL would disassemble and analyze 65 pits per year. Current floorspace allocation for the disassembly and surveillance of weapons components is 2,300 square feet (214 square meters). This would need to increase to 4,500 square feet (419 square meters) to support the levels of operations discussed in the Expanded Operations Alternative, including replication of the equipment in TA–55–4 that is necessary to support expanded operations.

II.A.3 Plutonium-238 Research, Development, and Applications

Plutonium-238 activities include research on radioisotopic thermoelectric generator design, fabrication, and testing, as well as plutonium oxide fuel recycle and processing, plutonium oxide heat-source recovery, disposition, and stabilization operations. The plutonium oxide removed from excess and retired radioisotopic thermoelectric generators and other heat sources received from Pantex, Sandia National Laboratories, and other facilities is processed at LANL. LANL would maintain the capability to conduct research, fabrication, and processing activities with plutonium-238 from both defense-related and nondefense-related heat sources. Because these are potentially high-dose operations, special glovebox lines are required. This function is not a candidate for transfer from TA–55–4 to the additional space because of the unique storage, handling, and processing requirements associated with this material, which could not be easily replicated. In addition, any space vacated by these activities in TA–55–4 would require equipment removal and decontamination prior to introducing other activities that could be compromised if contaminated with plutonium-238. Current floorspace allocation for the plutonium-238 processing activities is 9,000 square feet (837 square meters). This floorspace allocation would not change under the level of operations in the Expanded Operations Alternative.

II.A.4 Actinide Materials Science and Processing Research and Development

II.A.4.1 *Actinide Research and Development—General*

As part of the effort to better understand the material science aspects of nuclear materials and weapons aging and performance, various materials research activities are conducted at TA–55–4. Experiments also are conducted to evaluate the scientific underpinnings of stockpile activities, such as improved welding and bonding processes, development of special mold coatings, and fire-resistance tests. Some activities are related to dynamic experiments conducted by LANL and involve experiments at other sites as well as TA–55–4. Most of the actinide research and development involving aqueous materials would remain at TA–55–4. However, activities such as solid state synthesis and associated analyses (including both surface and bulk evaluations) could be transferred. Current floorspace allocation in TA–55–4 for general actinide research and development programs is 3,400 square feet (316 square meters) and would not change under the level of operations in the Expanded Operations Alternative in TA–55–4. However, some additional space would be needed. It is estimated that the space allocation for these actinide research and development activities would be 1,000 square feet (93 square meters) of contiguous space in addition to the 3,400 square feet (316 square meters) of space in TA–55–4.

II.A.4.2 *Actinide Research and Development—Environmental Management*

LANL provides continuing technical support to DOE's Office of Environmental Management (EM) regarding clean-up activities around the DOE complex, including process development for stabilization of residues. The efforts for EM are in three general areas, including: (1) issues associated with stabilization, chemical processing, storage shelf-life, surveillance, and skid-mounted processing techniques; (2) technology transfer to other sites or organizations involving mock-ups and operator training; and (3) stabilizing minor quantities of specialty items from other DOE sites. In effect, this effort builds on the capabilities of other TA–55–4 functions and demonstrates their application in these three areas. Because of its integral ties to other TA–55–4 functions, this is not a candidate to transfer to the additional space. Current floorspace allocations for EM technology support programs are 800 square feet (74 square meters).

II.A.4.3 *Special Recovery Line*

The Special Recovery Line supports the recovery of plutonium and other actinides from items that are potentially contaminated with tritium. LANL personnel would disassemble up to 40 items per year that are potentially contaminated with tritium. Current floorspace allocation for the Special Recovery Line is 700 square feet (65 square meters). Under the Expanded Operations Alternative, floorspace allocation for this would need to increase to 1,200 square feet (112 square meters). This function is a candidate for transfer from TA–55–4 to the additional space addressed in this PSSC analysis.

II.A.4.4 *Neutron Source Materials Recovery*

This function separates (recovers) radionuclides from light metals or light metal oxides to reduce the neutron radiation associated with excess neutron sources. Current and future floorspace allocation for neutron source material recovery programs is 800 square feet (74 square meters) in TA–55–4. Some of this work also is performed in the CMR Building at this time. Work performed in TA–55–4 depends extensively upon the unique plutonium processing and handling capability of TA–55–4. This is not a candidate for transfer from TA–55–4 to the additional space.

II.A.4.5 *Pit Disassembly and Material Conversion*

LANL has been tasked by DOE to develop and demonstrate pit disassembly and material conversion technologies. This is being done as part of the Advanced Recovery and Integrated Extraction System (ARIES). The ARIES can disassemble a pit by a cutting operation; convert the plutonium into plutonium metal or oxide; place the material in a welded storage container; and decontaminate and assay the container. This system currently exists in a series of gloveboxes in TA–55–4.

Under the Expanded Operations Alternative, LANL would conduct a one-time demonstration involving the disassembly of up to 250 pits and conversion of the plutonium to plutonium oxide as part of an integrated pit disassembly and conversion system, as opposed to a series of individual glovebox operations. This work would be done in TA–55–4 over a period of 4 years. The potential environmental impacts of this proposed action were analyzed in an environmental assessment (chapter 1, section 1.5.7, volume I) (DOE 1998).

The disassembly of pits, including those for surveillance and pit manufacturing purposes, would be an ongoing activity, at a level of up to 200 pit disassemblies per year, after the demonstration activities are completed. In order to accommodate the projected throughput for this process after demonstration, some expansion is anticipated. The disassembly portion of ARIES is very similar to the pit disassembly operations for surveillance. In this sense, these operations could be a candidate for transfer to the additional space. However, there are differences that make such a transfer very difficult. These include:

- The ARIES is still under development (as opposed to the disassembly for surveillance).
- The potential throughput of the integrated pit disassembly and conversion demonstration could make handling and packaging of the output materials between TA–55–4 and the additional space very costly.
- The space used for ARIES is not contiguous to the other space that would be made available by the other potential transfers. This means that if the ARIES space in TA–55–4 were made available, it would be difficult to use this space in an efficient manner.

All of these factors would make moving a portion of this capability to the additional space very costly and time consuming. For these reasons, DOE does not consider it reasonable to transfer this capability to the additional space. Note that some of the technologies used for pit disassembly in this project may be replicated and applied to disassembly and surveillance activities that are being considered for transfer (section II.A.2).

In summary, under the Expanded Operations Alternative, LANL would use ARIES in TA–55–4 for both the pit disassembly and conversion demonstration and for other pit disassembly needs at a level of up to 200 pit disassemblies per year. This alternative would result in the expansion of the ARIES space allocation from 1,000 square feet (93 square meters) to 1,500 square feet (140 square meters) in TA–55–4.

II.A.5 Fabrication of Ceramic-Based Reactor Fuels

LANL has been tasked by DOE to develop and demonstrate ceramic-based reactor fuels technology. A specific application of this function is to utilize output from pit disassembly and conversion (discussed under section II.A.4) for fabrication into mixed oxide (MOX) reactor fuel. Under the Expanded Operation Alternative, LANL personnel would demonstrate the ability to produce MOX fuel from older pits for use in nuclear reactors. Thus, for the next several years, this function is closely linked to the pit disassembly and material conversion function; DOE does not consider it appropriate to separate these two functions for the foreseeable future. Current floorspace allocation for the MOX demonstration activities is 3,000 square feet (280 square meters). This floorspace allocation would not change under the Expanded Operations Alternative. Similar to pit disassembly and conversion, this process would be a candidate for possible transfer to the additional space. The materials involved are metals and oxides, and the processes involved are not substantially different than those used for other processes considered for transfer. However, this process is closely linked to ARIES, and DOE does not consider it appropriate to separate these two functions. Therefore, as with ARIES, transfer of this process is not analyzed in this document.

II.A.6 Plutonium Recovery

Currently, LANL uses aqueous nitrate and chloride chemical techniques to extract plutonium from various residues. Processes include dissolution, ion exchange, solvent extraction, precipitation, pyrolysis, and carbonate oxidation/salt distillation. Pyrochemical recovery operations, or electrorefining, convert impure actinide metal to pure actinide metal. Plutonium recovery is a unique function in TA–55–4 that supports virtually all other activities in that facility. It is not feasible to transfer this function to the additional space. Current floorspace allocation for plutonium recovery is 13,400 square feet (1,246 square meters). No change in floorspace is anticipated for the Expanded Operations Alternative.

II.A.7 Support Activities

II.A.7.1 *Material Control and Accountability*

Material control and accountability is a support function for all operations at TA–55. Moreover, experience gained through this activity is directly applicable to the development and demonstration of nonproliferation technologies. The TA–55 nonproliferation technologies involve development of safeguards methodologies and instrumentation for plutonium nondestructive assay. A typical example is the development of nondestructive assay equipment for the ARIES program.

Plutonium nondestructive assay devices developed for nonproliferation purposes are routinely tested at TA–55–4. TA–55–4 provides LANL with a unique capability in the development of nonproliferation technology. TA–55 supports the development of safeguards instrumentation that contributes to nonproliferation technology. LANL would develop safeguards instrumentation for nonproliferation technologies; yet no dedicated floorspace would be allocated, because the equipment can be shared with various material management activities. This function is integral to other TA–55 functions and is not a candidate for transfer from TA–55 to the additional space.

II.A.7.2 *Materials Management and Radiation Control*

Materials management and radiation control include all support activities that track material movements to and from processing function spaces and storage areas, such as the TA–55–4 vault. Also, all facilities that process nuclear materials must allocate space for radiation measurement and control support staff. These support activities must be provided in facilities that handle nuclear materials. Current floorspace allocations for the material management and radiation control function are 4,400 square feet (409 square meters). No change to this floorspace allocation is anticipated for the level of operations addressed in the Expanded Operations Alternative in TA–55–4. It is also estimated that any functions transferred from TA–55–4 to the additional space would require similar support functions as well. It is estimated that the floorspace allocations for materials management and radiation control would require 2,000 square feet (186 square meters) in the additional space.

II.A.7.3 *Waste Management*

The plutonium processing and recovery programs produce waste materials that contain trace amounts of actinides. The presence of actinides requires that the waste materials be properly packaged and assayed prior to disposal. This is a support activity that must be provided for any facility handling nuclear materials. Current floorspace allocations for the waste management functions in TA–55 are 2,400 square feet (223 square meters). Floorspace allocations under the Expanded Operations Alternative for the waste management function are 2,400 square feet (223 square meters) in TA–55–4. It is estimated that the space allocation for this function in the additional space utilized would be 1,200 square feet (112 square meters).

II.A.7.4 *Analytical Chemistry—Metallography*

A core capability at TA–55 is the fundamental and applied analysis of plutonium using metallography. This supports the nuclear materials processing activities at TA–55–4. Current floorspace allocation for analytical chemistry metallography functions in TA–55–4 is 4,700 square feet (437 square meters). Future floorspace allocations for analytical chemistry metallography functions are 2,600 square feet (242 square meters) in TA–55–4. This reduction in floorspace is the result of including analytical chemistry functions that are specific to pit surveillance with the pit surveillance function and reduced floorspace requirements that result from improvement in analytical chemistry technologies. The analytical chemistry functions specific to pit surveillance are a candidate for transfer from TA–55 to the additional space, if pit surveillance is transferred also. This function would require 1,500 square feet (140 square meters) of floorspace in the additional space.

II.A.8 Contingency Space

Approximately 1,500 square feet (140 square meters) and 700 square feet (65 square meters) of contingency space would be allocated in TA–55–4 and the additional space facility, respectively. At this stage of design, contingency space is typically established to address the uncertainties in floorspace projections. This contingency amounts to about 3 percent of the total projected floorspace requirements.

APPENDIX II.B
ACCIDENT SCENARIO FOR BUILDING MODIFICATIONS AND UPGRADES OF STRUCTURES, SYSTEMS, OR COMPONENTS FOR THE ENHANCEMENT OF PIT MANUFACTURING OPERATIONS AT LANL

II.B.1 Preliminary Scenario Description

This scenario is based on a postulated accident during modifications or upgrades of structures, systems, or components at TA–55–4. The scenario is initiated by the accidental drop of a plutonium dioxide storage container during movement to or from storage, which is necessary to allow for building modification or upgrade activity. The container is assumed to rupture upon impact with the floor, resulting in an airborne release of particulate material. A worker is exposed. The suspended particulate material is processed through the ventilation system and released through the north exhaust stack.

II.B.1.1 *Scenario Description*

Description of the Activity

Storage containers, mostly metal, have been extensively used to package most of the radioactive material at TA–55 (LANL 1996a). It is postulated that prior to or during CMIP activities related to building modifications or upgrades at TA–55, some of these containers will be moved similar to routine movements that occur in TA–55–4 for operational purposes. Movements of this type present the potential for contamination spread in vaults and potential radiological exposures to personnel handling the containers (LANL 1996a). Although storage containers are typically intact, closed, and free of smearable contamination, some storage containers, after prolonged storage, may have been subjected to significant stresses as a result of chemical or physical changes in the stored material (LANL 1996a). Pages 3 through 135 of LANL 1996a may be consulted for additional details on the structural integrity of the various types of storage containers.

Frequency Range

This type of accident is expected to have a frequency of 0.1 to 0.01 per year assuming operation of ventilation and HEPA filtration, and a frequency of 10^{-2} to 10^{-4} per year in an unmitigated accident scenario (LANL 1996a). These are considered to be “anticipated” and “unlikely” events, respectively. Events necessary for the unmitigated version of this accident to occur and result in a release include: chance that the container is degraded, failure to follow procedures to inspect containers for visible signs of deterioration, failure of visual inspection to detect a deteriorated container, an accidental drop, breach of a degraded container upon impact with the floor, failure of the HVAC system, and failure or lack of HEPA filters. This assumes that, similar to operational requirements, activities related to building modifications or upgrades are restricted by procedure to inspect containers for visible signs of degradation or deformities. The frequency estimate of 10^{-2} to 10^{-4} per year for an unmitigated accident is conservative because: (1) the frequency of only a portion (accidental drop, maximum = 1×10^{-2} failure to follow an administrative procedure, maximum = 5×10^{-2} failure of visual inspection, maximum = 0.5) of the event sequence is 2.5×10^{-4}; therefore, quantification of additional events would likely place the sequence in a lower frequency; and

(2) it is likely that the ventilation system and associated filtration will be operable during upgrade activities (LANL 1998). On the other hand, the number of moves per year, if greater than 1.0, would increase the frequency.

Consequence Severity

A similar accident at TA–55–4 during normal operations has been estimated to result in a dose consequence to the MEI of 8.1 rem (committed effective dose equivalent [CEDE]) in the unmitigated scenario and a dose of 6.6×10^{-12} rem CEDE in a realistic scenario where the ventilation system and HEPA filtration are operable.

The worker who dropped the container would be exposed to a significant inhalation dose, but no acute worker fatality occurs. This inhalation dose would be expected to cause an increased risk of death from cancer over the worker's lifetime; however, this increase in risk is highly dependent on the following:

- The type of protective measures taken at the time of the accident
- The speed with which these measures are taken
- The effectiveness of medical treatment after the exposure

Thus, the risk to this worker cannot be predicted quantitatively or reliably.

ABOUT THE *NATIONAL ENVIRONMENTAL POLICY ACT*

The *National Environmental Policy Act* (NEPA) (42 United States Code [U.S.C.] §4321 *et seq.*) was enacted to ensure that federal decision makers consider the effects of proposed actions on the human environment and to lay their decisionmaking process open for public scrutiny. NEPA also created the President's Council on Environmental Quality (CEQ). The U.S. Department of Energy's (DOE's) NEPA regulations (10 Code of Federal Regulations [CFR] 1021) augment the CEQ regulations (40 CFR 1500 through 1508).

Under NEPA, an environmental impact statement (EIS) documents a federal agency's analysis of the environmental consequences that might be caused by major federal actions, defined as those proposed actions that may result in a significant impact to the environment. An EIS also:

- Explains the purpose and need for the agency to take action.
- Describes the proposed action and the reasonable alternative courses of action that the agency could take to meet the need.
- Describes what would happen if the proposed action were not implemented—the "No Action" (or status quo) Alternative.
- Describes what aspects of the human environment would be affected if the proposed action or any alternative were implemented.
- Analyzes the changes, or impacts, to the environment that would be expected to take place if the proposed action or an alternative were implemented, compared to the expected condition of the environment if no action were taken.

The DOE EIS process follows these steps:

- The Notice of Intent, published in the *Federal Register*, identifies potential EIS issues and alternatives and asks for public comment on the scope of the analysis.
- The public scoping period, with at least one public meeting, during which public comments on the scope of the document are collected and considered.
- The issuance of a draft EIS for public review and comment (for a minimum of 45 days), with at least one public hearing.
- The preparation and issuance of the final EIS, which incorporates the results of the public comment period on the draft EIS.
- Preparation and issuance of a Record of Decision, which states:
  - — The decision.
  - — The alternatives that were considered in the EIS and the environmentally preferable alternative.
  - — All decision factors, such as cost and technical considerations, that were considered by the agency along with environmental consequences.
  - — Mitigation measures designed to reduce adverse environmental impacts.
- Preparation of a Mitigation Action Plan, as appropriate, which explains how the mitigation measures will be implemented and monitored.

THE LOS ALAMOS NATIONAL LABORATORY SITE-WIDE ENVIRONMENTAL IMPACT STATEMENT PROCESS

The United States Department of Energy (DOE) has a policy (10 Code of Federal Regulations [CFR] 1021.330) of preparing a Site-Wide Environmental Impact Statement (SWEIS) for certain large, multiple-facility sites, such as the Los Alamos National Laboratory (LANL). The purpose of a SWEIS is to provide DOE and its stakeholders with an analysis of the environmental impacts resulting from ongoing and reasonably foreseeable new operations and facilities and reasonable alternatives at the DOE site. The SWEIS analyzes four alternatives for the continued operation of LANL to identify the potential effects that each alternative could have on the human environment.

The SWEIS Advance Notice of Intent, published in the *Federal Register* (FR) on August 10, 1994 (59 FR 40889), identified possible issues and alternatives to be analyzed. Based on public input received during prescoping, DOE published the Notice of Intent to prepare the SWEIS in the *Federal Register* on May 12, 1995 (60 FR 25697). DOE held a series of public meetings during prescoping and scoping to provide opportunities for stakeholders to identify the issues, environmental concerns, and alternatives that should be analyzed in the SWEIS. An Implementation Plan[1] was published in November 1995 to summarize the results of scoping, describe the scope of the SWEIS based on the scoping process, and present an outline for the draft SWEIS. The Implementation Plan also included a discussion of the issues reflected in public comments during scoping.

In addition to the required meetings and documents described above, the SWEIS process has included a number of other activities intended to enhance public participation in this effort. These activities have included:

- Workshops to develop the Greener Alternative described and analyzed in the SWEIS.
- Meetings with and briefings to representatives of federal, state, tribal, and local governments during prescoping, scoping, and preparation of the draft SWEIS.
- Preparation and submission to the Los Alamos Community Outreach Center of information requested by members of the public related to LANL operations and proposed projects.
- Numerous Open Forum public meetings in the communities around LANL to discuss LANL activities, the status of the SWEIS, and other issues raised by the public.

The draft SWEIS was distributed to interested stakeholders for comment. The comment period extended from May 15, 1998, to July 15, 1998. Public hearings on the draft SWEIS were announced in the *Federal Register*, as well as community newspapers and radio broadcasts. Public hearings were held in Los Alamos, Santa Fe, and Española, New Mexico, on June 9, 1998, June 10, 1998, and June 24, 1998, respectively.

Oral and written comments were accepted during the 60-day comment period for the draft SWEIS. All comments received, whether orally or in writing, were considered in preparation of the final SWEIS. The final SWEIS includes a new volume IV with responses to individual comments and a discussion of general major issues. DOE will prepare a Record of Decision no sooner than 30 days after the final SWEIS Notice of Availability is published in the *Federal Register*. The Record of Decision will describe the rationale used for DOE's selection of an alternative or portions of the alternatives. Following the issuance of the Record of Decision, a Mitigation Action Plan may also be issued to describe any mitigation measures that DOE commits to in concert with its decision.

---

1. DOE *National Environmental Policy Act* regulations (10 CFR 1021) previously required that an implementation plan be prepared; a regulation change (61 FR 64604) deleted this requirement. An implementation plan was prepared for this SWEIS.

Abstract: DOE proposes to continue operating the Los Alamos National Laboratory (LANL) located in Los Alamos County, in north-central New Mexico. DOE has identified and assessed four alternatives for the operation of LANL: (1) No Action, (2) Expanded Operations, (3) Reduced Operations, and (4) Greener. Expanded Operations is DOE's Preferred Alternative, with the exception that DOE would only implement pit manufacturing at a level of 20 pits per year. In the No Action Alternative, DOE would continue the historical mission support activities LANL has conducted at planned operational levels. In the Expanded Operations Alternative, DOE would operate LANL at the highest levels of activity currently foreseeable, including full implementation of the mission assignments from recent programmatic documents. Under the Reduced Operations Alternative, DOE would operate LANL at the minimum levels of activity necessary to maintain the capabilities to support the DOE mission in the near term. Under the Greener Alternative, DOE would operate LANL to maximize operations in support of nonproliferation, basic science, materials science, and other nonweapons areas, while minimizing weapons activities. Under all of the alternatives, the affected environment is primarily within 50 miles (80 kilometers) of LANL. Analyses indicate little difference in the environmental impacts among alternatives. The primary discriminators are: collective worker risk due to radiation exposure, socioeconomic effects due to LANL employment changes, and electrical power demand.

Public Comment and DOE Decision: The draft SWEIS was released to the public for review and comment on May 15, 1998. The comment period extended until July 15, 1998, although late comments were accepted to the extent practicable. All comments received were considered in preparation of the final SWEIS[1]. DOE will utilize the analysis in this final SWEIS and prepare a Record of Decision on the level of continued operation of LANL. This decision will be no sooner than 30 days after the Notice of Availability of the final SWEIS is published in the *Federal Register*.

VOLUME III
MEASUREMENTS AND CONVERSIONS

The following information is provided to assist the reader in understanding certain concepts in this SWEIS. Definitions of technical terms can be found in volume I, chapter 10, Glossary.

SCIENTIFIC NOTATION

Scientific notation is used in this report to express very large or very small numbers. For example, the number 1 billion could be written as 1,000,000,000 or, using scientific notation, as 1×10^9. Translating from scientific notation to a more traditional number requires moving the decimal point either right (for a positive power of 10) or left (for a negative power of 10). If the value given is 2.0×10^3, move the decimal point three places (insert zeros if no numbers are given) to the right of its current location. The result would be 2,000. If the value given is 2.0×10^{-5}, move the decimal point five places to the left of its present location. The result would be 0.00002. An alternative way of expressing numbers, used primarily in the appendixes of this SWEIS, is exponential notation, which is very similar in use to scientific notation. For example, using the scientific notation for 1×10^9, in exponential notation the 10^9 (10 to the power of 9) would be replaced by E+09. (For positive powers, sometimes the "+" sign is omitted, and so the example here could be expressed as E09.) If the value is given as 2.0×10^{-5} in scientific notation, then the equivalent exponential notation is 2.0E-05.

UNITS OF MEASUREMENT

The primary units of measurement used in this report are English units with metric equivalents enclosed in parentheses.

Many metric measurements presented include prefixes that denote a multiplication factor that is applied to the base standard (e.g., 1 kilometer = 1,000 meters). The following list presents these metric prefixes:

giga	1,000,000,000 (10^9; E+09; one billion)
mega	1,000,000 (10^6; E+06; one million)
kilo	1,000 (10^3; E+03; one thousand)
hecto	100 (10^2; E+02; one hundred)
deka	10 (10^1; E+01; ten)
unit	1 (10^0; E+00; one)
deci	0.1 (10^{-1}; E-01; one tenth)
centi	0.01 (10^{-2}; E-02; one hundredth)
milli	0.001 (10^{-3}; E-03; one thousandth)

micro	0.000001 (10^{-6}; E-06; one millionth)
nano	0.000000001 (10^{-9}; E-09; one billionth)
pico	0.000000000001 (10^{-12}; E-12; one trillionth)

DOE Order 5900.2A, *Use of the Metric System of Measurement*, prescribes the use of this system in DOE documents. Table MC–1 lists the mathematical values or formulas needed for conversion between English and metric units. Table MC–2 summarizes and defines the terms for units of measure and corresponding symbols found throughout this report.

RADIOACTIVITY UNIT

Part of this report deals with levels of radioactivity that might be found in various environmental media. Radioactivity is a property; the amount of a radioactive material is usually expressed as "activity" in curies (Ci) (Table MC–3). The curie is the basic unit used to describe the amount of substance present, and concentrations are generally expressed in terms of curies per unit of mass or volume. One curie is equivalent to 37 billion disintegrations per second or is a quantity of any radionuclide that decays at the rate of 37 billion disintegrations per second. Disintegrations generally include emissions of alpha or beta particles, gamma radiation, or combinations of these.

RADIATION DOSE UNITS

The amount of ionizing radiation energy received by a living organism is expressed in terms of radiation dose. Radiation dose in this report is usually expressed in terms of effective dose equivalent and reported numerically in units of rem (Table MC–4). Rem is a term that relates ionizing radiation and biological effect or risk. A dose of 1 millirem (0.001 rem) has a biological effect similar to the dose received from about a 1-day exposure to natural background radiation. A list of the radionuclides discussed in this document and their half-lives is included in Table MC–5.

CHEMICAL ELEMENTS

A list of selected chemical elements, chemical constituents, and their nomenclature is presented in Table MC–6.

APPENDIX A
WATER RESOURCES

A.1 SURFACE WATER NATIONAL POLLUTANT DISCHARGE ELIMINATION SYSTEM VOLUMES

One of the primary sources of potential impacts to surface water at the Los Alamos National Laboratory (LANL) is the National Pollutant Discharge Elimination System (NPDES) outfalls. NPDES outfall flow projections were prepared by alternative. Table A.1–1 identifies each industrial outfall by facility, outfall number, and watershed. The index discharge as of August 1996 is also presented along with outfall projections for each alternative.

A.2 GROUNDWATER HYDRAULIC PROPERTIES

The nature and extent of groundwater bodies in the LANL region has not been fully characterized. To better understand the hydrogeologic characterization of Pajarito Plateau, LANL personnel have prepared a Hydrogeologic Workplan (LANL 1998). The workplan proposes the installation of new wells that will further investigate the recharge and cross-connection mechanisms to the main aquifer (section 4.3.2.3). Current data indicate that groundwater bodies occur near the surface of the earth in canyon bottoms, alluvium, perched at deeper levels (intermediate perched groundwater), and at deeper levels in the main aquifer. Table A.2–1 presents summary information on the hydraulic parameters of groundwater bodies in the LANL region.

A.3 MAIN AQUIFER VOLUME ESTIMATES

The main aquifer is the only groundwater body within the LANL region that is sufficiently saturated and permeable to transmit economic quantities of water to wells for public use. Recharge of the main aquifer is not fully understood nor characterized. Recent investigations suggest that the majority of water pumped to date from the main aquifer has been from storage, with minimal recharge (Rogers et al. 1996). Because this groundwater body is the only source of potable water within the region, the amount of water available for future use is of interest to many.

For the purposes of the Site-Wide Environmental Impact Statement (SWEIS), water storage calculations were made using a model developed by the United States (U.S.) Geological Survey (USGS). For modeling regional flow in the main aquifer, USGS subdivided the main aquifer into eight layers, which have a total thickness of 5,600 feet (1,707 meters) (Figure A.3–1). The model grid uses 25 columns and 33 rows spaced at 1-mile intervals. The volume of water stored in any given cell is equal to the storage coefficient multiplied by the volume of the cell. For all cells, a value of 0.1554 was used for the storage coefficient, which was based on a specific yield value of 0.15 and specific storage capacity of 1×10^{-6} per foot. The volume of water stored beneath any given region is the sum of water stored in the cells, bounded by the region, and extending to the total depth of the aquifer.

The volume for the main aquifer beneath the Española Basin is underestimated by this model, as the basin actually extends beyond the modeled region (Figure A.3–2). Table A.3–1 presents a summary of the values used to calculate the amount of water stored in the main aquifer beneath the Pajarito Plateau (which is a subset of the total area that USGS modeled), the area from which the Department of Energy (DOE) water is drawn. Table A.3–2 presents a

TABLE A.1–1.—*Volume of NPDES by Watershed for Index and Alternatives*[a]-Continued

FACILITY[f]	OUTFALL	LEGEND[g]	TA[e]	BLDG.	DESCRIPTION[h]	WATERSHED	DISCHARGES[b] (MILLIONS OF GALLONS PER YEAR)				
							INDEX (08/96)	NO ACTION	EXPANDED OPERATIONS	REDUCED OPERATIONS	GREENER
	Sum, Non-Key Facilities				28 Outfalls[c,d]		130	261	142	142	142
	LANL Total						233	261	278	218	275

[a] NPDES Information Sources: Index information was provided by the Surface Water Data Team Reports of August 1996 (Bradford 1996) and as modified in 1997 (Garvey 1997). Outfall flow projections for the alternatives were based on the outfalls remaining as of November 1997.
[b] When no discharge is indicated under the alternative, this means the outfall was eliminated. For outfalls with 0.00 flow, this means the outfall still remains but the projected flow is so small that it was rounded down to zero.
[c] All effluent from the TA–46 Sewage Treatment Facility Sanitary Waste System Consolidation (SWSC) is pumped to a re-use tank adjacent to the TA–3 power plant. When the power plant is in operation, water is drawn from the tank as make-up for the power plant cooling towers where it is either lost to the air through evaporation or discharged to Sandia Canyon via the power plant Outfall 01A-001. For the index flow, of the total 77.9 MGY flow for Outfall 01A-001, approximately 29.0 MGY is contributed by SWSC as make-up water. For the other four alternatives, of the total 113.9 million gallons per year (MGY) flow for Outfall 01A-001, approximately 65 MGY is contributed by SWSC as make-up water. Outfall 135 is located at the TA–46 SWSC facility but is not used. Outfall 13S, although not listed in the table, is added to the number of outfalls, making a total of 28 outfalls for the non-key facilities.
[d] Number of outfalls identified, 59 and 28, for key and non-key, respectively, are for the index outfalls. The number of outfalls for all the alternatives is 33 and 28 for key and non-key, respectively. This reduction in outfalls from the index for key facilities is due to LANL's ongoing Outfall Reduction Program. Outfall flow projections for the alternatives were based on the outfalls remaining as of November 1997.

Source: Frenzel 1995

summary of the values used to calculate the water stored in the main aquifer within the area studied by the USGS (Figure A.3–2). These two tables also reflect the number of years it would take to deplete the water stored beneath these areas for each level modeled based on 100 percent use of water rights by the major users who draw from these areas. The total water rights used for these calculations are reflected in Table A.3–3.

It should be noted that these calculations do not consider recharge to or discharge from the aquifer or pumping from wells outside the control volume (e.g., Española, Santa Fe, San Ildefonso wells). Also, the water level changes projected by the regional MODFLOW model represent average changes over a whole grid-cell (i.e., a square that is a mile on a side). They are for the most part not predictive of the water level changes at any single point within the cell (for example, a supply well). Pumping wells have characteristic "cones of depression" where the water surface reflects an inverted cone, and water levels at the well may be quite different from levels even a few ten's of feet away. Whether any individual well would exhibit water level changes consistent with the predicted grid-cell average change is a function of, for example, its location within the grid-cell; proximity to other pumped wells; and the individual well operation, construction, and hydraulics. Hence, the water level changes predicted by the model can only be considered qualitatively and not be considered as finite changes.

TABLE A.3–3.—*Water Rights for Española Basin*

A.4 DEVELOPMENT OF GROUNDWATER MODEL INPUT FILES

A.4.1 Water Use Projections

Table A.4.1–1 presents annual water use projections. The following processes were used to generate the numbers shown in Table A.4.1–1:

- *LANL Water Use.* The SWEIS alternatives were reviewed to determine changes in water use across LANL. Because technical area (TA)–53 is a major user of water at LANL and is individually metered for water use, projections for this facility were made separate from the rest of LANL.

  While projections for maximum annual use were developed for the SWEIS under each alternative (for comparison to the DOE Water Rights in the Socioeconomic Analyses in chapter 5), use rates for each of the next 10 years were developed separately for the purposes of assessing drawdown of the main aquifer. These annual projections, were developed using the average annual LANL use from 1990 through 1994 (LANL 1992, LANL 1993, LANL 1994, LANL 1995, and LANL 1996). This baseline value was used for the 10-year projections, to which facilities use data (based on projected construction and operations in each alternative) were added or subtracted as appropriate. These projections include reductions of 26 million gallons (99 million liters) per year, due to the TA–16 steam plant upgrade, and 10 million gallons (38 million liters) per year, due to the High Explosives Wastewater Treatment Facility upgrade.
- *Los Alamos County Water Use.* Data from 1990 through 1994 indicate an average per

TABLE A.4.1–1.—*Annual Water Use Projections*

PERCENTAGE OF DOE WATER RIGHT (1,805 MILLION GALLONS)											
No Action	86%	86%	85%	85%	90%	90%	90%	90%	90%	90%	90%
Expanded Operations	94%	94%	92%	92%	97%	97%	97%	97%	97%	97%	97%
Reduced Operations	81%	81%	80%	80%	81%	81%	80%	80%	80%	80%	80%
Greener	91%	91%	89%	89%	94%	94%	94%	94%	94%	94%	94%

capita use of 155.8 gallons (589.7 liters) per day. This per capita use was applied to conservative projections (these are considered conservative because limited land availability would likely prevent the population from growing anywhere near the maximum projection) for the county population as follows: No Action, 18,969; Expanded Operations, 19,924; Reduced Operations, 17,394; and Greener, 18,969. These numbers were assumed constant through the entire 10-year period, effective January 1, 1996. These numbers were multiplied by the average per capita use figure to obtain the total Los Alamos County use figures shown. Bandelier water use is included in these calculations, because the per capita use factor included data from Bandelier.

The total use from DOE Water Rights was calculated by adding the results of the LANL use calculations and the Los Alamos County calculations.

- *Santa Fe County Water Use*. The Santa Fe County population figures used to calculate water use (Table A.4.1–2) were based on projected populations at 5-year intervals, prepared by the University of New Mexico's (UNM's) Bureau of Business and Economic Research (UNM 1994). A second-order polynomial was fit to the data to calculate the annual numbers shown in the second column. The number of new consumers for the public system was calculated based on estimates from Sangre de Cristo Water Company, because new developments are expected to use less water (142 gallons [540 liters] per day per person) than existing users (172 gallons [654 liters] per day per person). The per capita figure averages include irrigation and industrial use. To calculate the total public system water use, the percentage of Santa Fe County served by the Sangre de Cristo Water Company (57 percent) was assumed constant. For years 1996 through 2006, the projected water increases based on per

TABLE A.4.1–2.—*Estimated Annual Water Use for Santa Fe County*

YEAR	SANTA FE COUNTY POPULATION PROJECTION	NEW CONSUMERS	TOTAL WATER USE (gal./yr)	TOTAL WATER USE (acft/yr)
1993	105,089		3,741,505,919	11,481.5

gal./yr = gallons per year
acft/yr = acre-feet per year

capita increases were added to the actual water use value for 1995.

A.4.2 Other Input Files and Information

Frenzel's model (1995) for north-central New Mexico, was used with no changes to any hydraulic parameters and no additional calibration. Data on water use from individual DOE and Santa Fe wells from 1993 through 1995 were obtained from the state engineers office and added to Frenzel's well input file, which used pumping data through 1992 (Frenzel 1995). Changes were made only to well pumping rates calculated from the water use projections. The process below describes the procedure for reducing annual total well field production to pumping from each model layer for each individual well. This process was performed for each alternative.

- To allocate the total use for the DOE and Santa Fe supply systems among individual wells, a spreadsheet was developed to calculate average percentage of the total produced by each well field from 1993 through 1995. In turn, the average proportion of the total well field production supplied by each individual well within the field was calculated from 1993 through 1995.
- For projected pumping rates for each well based on water use projections, a spreadsheet was developed based on Frenzel's (1995) Table 11. Frenzel's Table 11 allocates the percentage of pumping from layers one through five for each well. These percentages were multiplied by each well's total annual projected pumping to obtain the proper flow rate from each layer.
- Based on conversations with representatives of the Sangre de Cristo Water Company (Santa Fe County's public supplier) in 1995, Santa Fe plans to start taking their San Juan-Chama water right (5,605 acre-feet [or 1,827 million gallons (6,913 million liters)] per year) from the Rio Grande through a diversion pipeline (Santa Fe Diversion). When the collection system for the Rio Grande is on-line, Santa Fe will shut down the Buckman well field and use it only for supply emergencies.

A.5 MODEL RESULTS

Based on the Frenzel model, the total approximate volume of water within the 5,600-foot (1,707-meter) thickness of the main aquifer below the Pajarito Plateau is estimated to be 21.8 trillion gallons (82,513 million cubic meters). Water quality will generally become increasingly poor with increasing depth. Therefore, the amount of potable water may be far less than the total volume available. Available data are insufficient to model water quality degradation with depth; but, water supply wells screened as deep as 1,830 feet (558 meters) into the main aquifer produce potable water that meets *Safe Drinking Water Act* standards (42 United States Code [U.S.C.] §300).

A similar water storage analysis for the main aquifer beneath the entire USGS modeled area shows that 106 trillion gallons (401 trillion liters) of water are stored. This estimate of storage volume is conservative, as the USGS model does not include the entire Española Basin. Use of groundwater from the Española Basin at combined annual water rights rates for DOE (1,805 million gallons [6,832 million liters] per year); Santa Fe (7,012 million gallons [26,540 million liters] per year); and Española (906 million gallons [3,429 million liters] per year) indicates that if the upper 1,275 feet (389 meters) of the Basin were used, a water supply would be available for 2,982 years and if the upper 2,000 feet (610 meters) of the Basin were used, a water supply would be available for 4,637 years.

A.5.1 Changes in Water Levels and Storage in the Main Aquifer

The model results reflect water level changes at the top of the main aquifer across the alternatives, given continued draw from the aquifer by DOE, Española, and Santa Fe. Table A.5.1–1 shows predicted water level changes at the surface of the main aquifer during the period from 1996 through 2006 for each of the SWEIS alternatives. Although the water use modeled includes water use in Española and Santa Fe, the differences between the alternatives are due only to LANL operations.

The groundwater model indicates that no springs in White Rock Canyon are likely to go dry. Springs in White Rock Canyon in the vicinity of the Buckman well field may actually increase in flow due to rising groundwater levels (from 0.1 to 3.8 feet [0.03 to 1.2 meters]). The rising water levels result from the continuing recovery in the vicinity of the Los Alamos well field, which was shut down in 1992, and recovery in the vicinity of Santa Fe's Buckman well field, which is planned for shut down in 1999. Operations of both well fields are independent of the alternatives and significantly affect water levels in the main aquifer in the vicinity of the Rio Grande.

TABLE A.5.1–1.—*Maximum Water Level Changes at the Top of the Main Aquifer Due to All Users Combined (1996 Through 2006)*

	WATER LEVEL CHANGE IN FEET[a]			
	NO ACTION	**EXPANDED**	**REDUCED**	**GREENER**

Los Alamos Well Field	+3.8	+3.8	+3.8	+3.8
East of Rio Grande:				
Household, Community Wells	0.0	0.0	0.0	0.0

[a] Negative value (-) indicates water level drop; positive value (+) indicates water level rise.

In comparison to the thicknesses of the eight model layers (total equals 5,600 feet [1,707 meters]), the maximum drawdown predicted over the next 10 years for DOE well fields (15.6 feet [4.8 meters] for the Pajarito well field) represents a reduction of main aquifer saturated thickness of 0.28 percent. Water use projections indicate that the maximum total volume of water to be withdrawn from DOE well fields from 1996 through 2006 is 19 billion gallons (72 billion liters), which is 0.09 percent of the main aquifer volume (22 trillion gallons [83 trillion liters]) of water in storage beneath the Pajarito Plateau. In summary, the drawdowns in DOE well fields are minimal relative to the total thickness of the main aquifer, and the volume of water to be used over the period from 1996 through 2006 is negligible relative to the volume of water in storage.

The water level declines reflected here could have an impact on the water levels in off-site wells that are used by other entities, which would require these entities to drill deeper wells into the aquifer.

A.6 MODEL UNCERTAINTIES AND LIMITATIONS

The following uncertainties and limitations associated with the use of this model should be noted:

- The model only includes a portion of the main aquifer. No model or method exists to predict changes of water levels in the vicinity of springs emanating from intermediate perched groundwater bodies (Basalt Spring, S-Site (TA–16) Springs, Water Canyon Gallery).
- The model's mile-square grid spacing underestimates drawdowns at individual wells. The grid spacing is also too large to precisely model changes in water levels in the main aquifer adjacent to the Rio Grande in response to the Santa Fe diversion. A finer-scale model is under development by the Sangre de Cristo Water Company.
- No additional calibration was performed, even though Otowi-4 pumping, initiated after Frenzel's model was calibrated, may make additional calibration technically desirable.
- Because water levels at the Pueblo of San Ildefonso are not available, modeled water level changes are the only data available.
- The remainder of Santa Fe County is served by approximately 16,000 domestic wells, each of which has rights to 3 acre-feet (0.98 million gallons [3.7 million liters]) per year. These are far more private wells than were included in the model (200). This factor probably does not significantly change model drawdown results for the following reasons: most private users probably use much less than 3 acre-feet (0.98 million gallons [3.7 million liters]) per year, the private wells extract only from layer one or shallower perched zones (public supply wells pump from layers two through five), and private wells are sufficiently spread out so that impacts from one location are not observed at other nearby wells.

APPENDIX B
AIR QUALITY

This appendix provides supplemental information regarding the air quality analyses presented in chapter 5. This appendix addresses aspects of both radiological air emissions and nonradiological air emissions.

B.1 RADIOLOGICAL AIR QUALITY

B.1.1 Methodology

The radiological air quality analyses address:

- *Facility-Specific Maximally Exposed Individual (FS MEI)*—The FS MEI represents a location near a facility that is modeled as having the greatest dose to a hypothetical public individual from all modeled emissions under a given SWEIS alternative.
- *LANL Site-Wide Maximally Exposed Individual*—The LANL MEI represents the location of the single highest modeled dose to a hypothetical public individual. Under a given alternative, the highest FS MEI becomes the LANL MEI for that alternative.
- Collective dose to the population within a 50-mile (80-kilometer) radius from LANL.

In addition to these receptors, isodose maps were developed that show the estimated committed effective dose equivalents (CEDEs) at any location within the 50-mile (80-kilometer) radius. These maps were developed to allow individuals within the 50-mile (80-kilometer) radius to estimate their modeled CEDE.

In order to enable these analyses, a review of historical emissions was undertaken for the period 1990 through 1994. The data were largely derived from past National Emission Standards for Hazardous Air Pollutants (NESHAP) reports. The data reviewed are summarized in Table B.1.1–1. The data show the CEDE to the LANL MEI. Although valid, these data were only available for the LANL MEI, not for the FS MEI.

MEIs are hypothetical individuals who do not leave and do not take protective actions to avoid exposure. The risk from ionizing radiation consists mostly of some number of excess latent cancer fatalities (LCFs). These are cancers resulting from, and that develop well after, the exposure to ionizing radiation. These represent an increase in the number of fatal cancers that occur from other causes. The excess LCF is the product of the dose and the risk factor of 5×10^{-4} excess LCF per person-rem. The reader should recognize that these estimates are intended to provide a conservative measure of the potential impacts to be used in the decision-making process and do not necessarily portray an accurate representation of actual anticipated fatalities. In other words, one could expect that the stated impacts form an upper bound and that actual consequences could be less, but probably would not be worse. This is discussed in the primer on the effects of radiation in section D.1 of appendix D, Human Health.

B.1.1.1 *Modeled Facilities*

Several facilities at LANL emit radioactive materials to the ambient air through stacks, vents, or diffuse emissions. Not all of the facilities listed in Table B.1.1–1 were modeled for this SWEIS. Those facilities not modeled were eliminated from such detailed analysis because they have historically low emission rates or because they are not expected to operate during the period analyzed in the SWEIS. The facilities modeled include 16 emission points from 12 facilities within 10 TAs. These facilities are listed in Table B.1.1.1–1. These

TA–48	Radiochemistry Laboratory
TA–53	LANSCE[a]
TA–54	Area G
TA–55	Plutonium Facility

Notes:
[a] Five specific sources were modeled from TA–53. These include the TA–53 Exhaust Stack-2 (ES–2), Exhaust Stack-3 (ES–3), Isotope Production Facility (IPF), Low- Energy Demonstration Accelerator (LEDA), and combined diffuse emissions.
CMR = Chemistry and Metallurgy Research, WETF = Weapons Engineering Tritium Facility, LACEF = Los Alamos Critical Experiments Facility, TSTA = Tritium System Test Assembly, TSFF = Tritium Science Fabrication Facility

facilities historically have emitted the majority of radioactive materials to the air or were affected by the SWEIS alternatives.

Emission projections were made by alternative for each of these facilities. These estimates were based on historical activity levels and emissions and the SWEIS alternative descriptions. These estimates served as the basis for modeling the consequences of LANL radiological air emissions.

B.1.1.2 *Selection of the CAP–88 Model*

Based on estimated emission rates under various alternatives, air dispersion modeling was performed to evaluate the radiation doses (CEDEs) from these emissions. The *Clean Air Act* Assessment Package-1988 (CAP–88) (EPA 1992a) is one such air dispersion model. It was selected to perform dose calculations. CAP–88 contains a modified Gaussian plume model that estimates the average dispersion of radionuclides released from up to six sources simultaneously. The model may be run on individual sources as well. The sources may be elevated stacks or uniform area (diffuse) sources. The program computes radionuclide concentrations in air, rates of deposition on ground surfaces, concentrations in food from radionuclides emitted to the air, and intake rates for people from ingestion of food produced in the assessment area. The model calculates the CEDE resulting from these air emissions and resulting exposure pathways.

CAP–88 was chosen for the following reasons:

- CAP–88 is approved by the U.S. Environmental Protection Agency (EPA) for demonstrating compliance with the NESHAP (40 Code of Federal Regulations [CFR] 61, Subpart H) and is used by LANL and other DOE facilities for that purpose. Consequently, DOE and LANL have experience with this code, and it is acceptable to other regulatory agencies.
- CAP–88 is known to compare favorably with other models for producing results that generally agree with experimental data.
- To support NESHAP estimates, the LANL mainframe version of CAP–88 was previously modified to include special radionuclides emitted by the Los Alamos Neutron Science Center (LANSCE). Those radionuclides are mainly activation products that are not modeled by the personal computer version or by other air dispersion models, such as the Generation II (GENII) model prepared for DOE by Pacific Northwest Laboratory.
- CAP–88 adequately accounts for both point sources and diffuse sources, which are both present at LANL.

- Other models (such as GENII) do not have any significant advantages over CAP–88 that would negate its use.

B.1.1.3 *Limitations of the CAP–88 Model*

As in all computer models, there are some limitations in the CAP–88 model. These limitations were considered prior to the use of this model but were dismissed. The most important limitations are described below.

- While up to six sources can be modeled in a single run, all the sources are assumed to be at the same geographic point during the modeling run. This was overcome by performing separate model runs for each source.
- CAP–88 assumes a flat terrain during the radionuclide transport. Complex terrain cannot be modeled by CAP–88. This effect was considered negligible when the distance to the exposed individuals is large compared to the stack height, area, or facility size. The flat terrain model is customary and used elsewhere to model LANL emissions.
- The model assumes that individuals remain at locations 24 hours a day, 365 days a year, when estimating the dose for that specific location. This is obviously unlikely but provides worst-case bounding conditions.
- CAP–88 calculates the dose from external radiation from radionuclides in the air that envelops the receptor. However, if the radionuclide cloud is only overhead and not in touch with the ground, the radiation dose is not calculated. This is not regarded as a serious shortcoming because of the absorption of the radiation in air and CAP–88's overestimate of the dose once the cloud has touched down. In most past years, environmental monitors have shown lower exposures than were calculated using CAP–88.

B.1.1.4 *Model Input Parameters*

The CAP–88 model requires many input parameters in order to perform dose calculations. Most of these parameters are built into the model and require no input from the user. However, some parameters (such as the amount of radionuclide emitted) must be introduced by the user. These user-defined inputs are discussed below, along with how the data were derived.

Radionuclide Emission Rate Data

Radionuclide emission rate projections for each alternative were introduced into the CAP–88 model. Some modeled facilities have more than one emission point, depending on the operations within the facilities. For example, TA–53 has five emission points, which were modeled separately. The radionuclides emitted and their modeled emission rates for each facility are summarized in Tables B.1.1.4–1 through B.1.1.4–17.

All radionuclide emissions were modeled using the personal computer version of CAP–88, except when the radionuclides contain mixed activation products (MAPs). In those cases, the LANL mainframe version of CAP–88 was used for modeling. The only two modeled facilities that required the use of LANL mainframe computers were TA–48 and TA–53.

Some assumptions had to be made while modeling some radionuclide emissions from LANL. In all cases, the most conservative assumption was selected for use, resulting in an overestimation of the committed effective dose equivalents. These assumptions are:

- Actinide and particulate emissions from the Chemistry and Metallurgy
- Research (CMR) Building and TA–55 were not modeled by radionuclide. All actinide and particulate emissions from these facilities were assumed to be plutonium-239.

TABLE B.1.1.4–1.—*Radiological Air Emissions from TA–3–29 (CMR)*

STACK NUMBER	WING 2	WING 4	WING 9
	ES–14	ES–24	ES–46
STACK PARAMETERS			
Height (meters)	15.9	15.9	21.5
Diameter (meters)	1.1	1.1	2.1
Exit Velocity (meters per second)	6.8	14.6	1.9
EMISSION RATE PER STACK (CURIES PER YEAR)			
No Action Alternative			
Actinides (plutonium-239)[a]	0.000420		
Expanded Operations Alternative			
Actinides (plutonium-239)[a]	0.000760		
Fission Products[b]			
Krypton-85			100
Xenon-131m			23,480
Xenon-133			1,500
Tritium[c]		1,000	
Reduced Operations Alternative[d]			
Actinides (plutonium-239)[a]	0.000380		
Greener Alternative[d]			
Actinides (plutonium-239)[a]	0.000420		

Notes:
[a] Actinides were not broken down by isotope; therefore, they were represented by plutonium-239. Actinides are emitted from Wings 2, 3, 4, 5, 6, 7, and 9, but no stacks were specified. The most conservative stack was chosen (ES–14 at Wing 2) to model emissions from all these wings.
[b] Fission product emissions apply only to the Expanded Operations Alternative. Fission products are emitted from Wing 9. The most conservative stack (ES–46) was chosen for modeling.
[c] Tritium emissions apply only to the Expanded Operations Alternative. Tritium is emitted from Wing 4. A new stack will be installed for it; no information on the stack parameters is available. The most conservative stack (ES–24) was chosen to model all tritium emissions from Wing 4.
[d] The No Action and Greener Alternatives are the same. The Reduced Operations Alternative is 90 percent of the No Action Alternative.

Uranium-238	0.0000122	0.0000122	0.0000122	0.000275	0.000275	0.0000244
Greener Alternative						
Uranium-234	0	0	0	0	0	0.0000220
Uranium-238	0.0000122	0.0000122	0.0000122	0.000275	0.000275	0.0000244

Notes:

[a] 90 percent of the depleted uranium (DU) (e.g., uranium-238) comes out of ES–13 and ES–24 (i.e., 45% each).

[b] No stack information is available for enriched uranium (EU) emissions; therefore, the most conservative emission stack (ES) is considered for emissions (stack ES–25).

[c] Stack ES–26 is added to stack ES–25 for similarity of parameters.

[d] All uranium-238 is assumed to be in equilibrium with thorium-234 and protactinium-234m. All DU is considered as uranium-238, and all EU is considered as uranium-234.

[e] The No Action, Greener, and Reduced Operations Alternatives are the same. The Expanded Operations Alternative is three times higher than the No Action Alternative.

TABLE B.1.1.4–3.—*Radiological Air Emissions from TA–11 (High Explosives Testing)*

RADIONUCLIDE	ALTERNATIVE (CURIES PER YEAR)			
	NO ACTION	EXPANDED OPERATIONS	REDUCED OPERATIONS	GREENER
Uranium-238[a]	3.98×10^{-7}	9.96×10^{-7}	2.32×10^{-7}	2.32×10^{-7}
Uranium-235[b]	7.56×10^{-9}	1.89×10^{-8}	4.41×10^{-9}	4.41×10^{-9}
Uranium-234[c]	1.49×10^{-7}	3.71×10^{-7}	8.67×10^{-8}	8.67×10^{-8}

Notes:
[a] Protactinium-234m and thorium-234 are in equilibrium with uranium-238.
[b] Thorium-231 is in equilibrium with uranium-235.
[c] No stack emissions. This is an area source. An area of 10,000 square meters (m^2) was used. Areas of 100 and 1,000 m^2 were also used, with no difference in the results.

TABLE B.1.1.4–4.—*Radiological Air Emissions from TA–16 (Tritium Facility)*

RADIONUCLIDE[a,b]	ALTERNATIVE (CURIES PER YEAR)			
	NO ACTION	EXPANDED OPERATIONS	REDUCED OPERATIONS	GREENER
Tritium (gaseous)	100	300	100	100
Tritium (water vapor)	300	500	300	300
Total	400	800	400	400

Notes:
[a] Tritium is emitted in the gaseous form (HT) as well as in the water vapor form (HTO). CAP–88 uses the water vapor form of tritium for modeling for a conservative result because the vapor form produces the highest dose. It was assumed that all tritium is in the vapor form.
[b] Tritium is emitted from fan exhaust (FE)–4 in Building 205 (the only stack for tritium emissions at TA–16). The stack parameters are: Height = 18.3 meters, Diameter = 0.5 meter, and Exit Velocity = 19.3 meters per second.

TABLE B.1.1.4–5.—*Radiological Air Emissions from TA–18 (Pajarito Site)*

RADIONUCLIDE[a,b]	ALTERNATIVE (CURIES PER YEAR)			
	NO ACTION	EXPANDED OPERATIONS	REDUCED OPERATIONS	GREENER
Argon-41	101	126	101	101

Notes:
[a] No stack emissions. This is an area source. An area of 45,200 square meters (m^2) was calculated based on the air volume used by LANL to calculate the emission rates.
[b] Argon-41 is the only significant radionuclide emitted from TA–18. Others are present in quantities too small to consider in this analysis.

TABLE B.1.1.4–6.—*Radiological Air Emissions from TA–21 (Tritium Facility)*

	NO ACTION	EXPANDED OPERATIONS	REDUCED OPERATIONS	GREENER
Argon-41	2.56	3.2	1.28	3.2
Carbon-11	61.44	76.8	30.72	76.8

Notes:
[a] TA–53 emissions were divided into five sources: ES–2 stack emissions, ES–3 stack emissions, LEDA emissions, IPF–2 emissions, and diffuse emissions.
[b] Diffuse emissions: escape from the area around the high intensity beam line (Line A). No stack emissions.

- All uranium-238 emissions were assumed to be in equilibrium with its decay daughters, thorium-234 and protactinium-234m.
- Unidentified mixed fission products (MFPs) or MAPs are modeled as strontium-90/yttrium-90 in equilibrium. This was done for some unidentified MAPs from the Low Energy Demonstration Accelerator (LEDA) emissions at the LANSCE and for some MAPs and MFPs from TA–48.
- Tritium can exist in gaseous (elemental tritium) or water vapor (tritium oxide) forms. The oxide form is used in CAP–88 to ensure conservative results because it produces a higher dose. All tritium emissions were modeled as oxides from TA–16 and TA–21 (the tritium facilities).

Source Parameters

LANL emission sources include individual stacks and large area (diffuse) sources. For stack emissions, the actual stack heights, diameters, and exit velocities were used. These stack parameters are reflected in Tables B.1.1.4–1 through B.1.1.4–17.

The sizes of area sources were calculated based on site information. Because the sizes of area sources could not always be precisely determined, a sensitivity analysis was performed using various area sizes. This analysis was performed by changing the sizes of the areas modeled while fixing all other parameters. Areas of 1,075, 10,750, and 107,500 square feet (100, 1,000, and 10,000 square meters) were used in separate model runs for the same case, and the results in all three runs were exactly the same. The conclusion was that the resultant dose was independent of the size of the area source if the radionuclide emission rates was the same due to the distance of the modeled MEI or member of the population from the area source. Despite this sensitivity analysis, the best estimate of an area's size was used in all cases for the actual modeling.

Agricultural Data

Radionuclides emitted to the air and subsequently ingested with food crops is one pathway of exposure used by CAP–88. The immediate region surrounding the LANL site does not have any major agricultural production activities; however, the agricultural data used in the modeling effort are reflected in Table B.1.1.4–18 (EPA 1992a).

These agricultural data were provided in the CAP–88 database for the State of New Mexico. Using these parameters may have resulted in an overestimate of the dose to individuals living in close proximity to the LANL site.

Meteorological Data

Meteorological data are used in conjunction with the CAP–88 model to estimate air dispersion of emitted nuclides. There were four meteorological towers distributed over the LANL sites used for this purpose. The meteorological data used for each tower were the average of 3 years of actual meteorological data. The tower nearest to the modeled facility was used for input data, as reflected below.

TABLE B.1.1.4–18.—*Fraction of Agricultural Products Produced in the Home, Assessment Area, and Imported*

	VEGETABLE	MILK	MEAT
Fraction Home Produced	0.7	0.399	0.442
Fraction Assessment Area Produced	0.3	0.601	0.558
Fraction Imported	0	0	0

- *TA–6 Tower*—Used for modeling emissions from TA–3, TA–16, TA–48, and TA–55
- *TA–49 Tower*—Used for modeling emissions from TA–15 and TA–36
- *TA–53 Tower*—Used for modeling emissions from TA–21 and TA–53
- *TA–54 Tower*—Used for modeling emissions from TA–18 and TA–54

The use of 3 years' data for modeling purposes is due to the fact that these towers have existed in these locations for that period of time. The use of average meteorological data over this period is expected to reflect future conditions more accurately than data from any individual year.

Other meteorological data needed as input to CAP–88 are:

- Annual precipitation = 19 inches (48 centimeters) per year (Bowen 1990)
- Annual ambient temperature = 48°F (8.8°C) (Bowen 1990)
- Height of lid = 5,000 feet (1,525 meters) The lid height (vertical extent of mixing of air emissions) was obtained from the weather center in Albuquerque and was verified by the National Oceanographic and Atmospheric Administration.

Distances Between Emission Points and Receptors

The distances between the emission sources and the specific location modeled must be introduced as input parameters for CAP–88 to calculate the nuclide concentration and subsequent doses at that location. Map coordinates for each source at LANL and each receptor location were determined using large maps and Geographic Information System (GIS) graphics. The distances were then calculated using these coordinate points. The distances and direction between each modeled facility and the facility-specific MEI location are listed in Table B.1.1.4–19.

Population Data

Data regarding the population distribution within a 50-mile (80-kilometer) radius around LANL are needed by CAP–88 for the calculation of the collective population dose. LANL has been using a population data file that was prepared based on the 1990 Census (DOC 1991). A new population data file was prepared by the University of Nevada (UN) in 1995, using data from the New Mexico Bureau of Business and Economic Research (BBER 1995). The UN data file was used for all CAP–88 population runs, consistent with the socioeconomic data used for the SWEIS. There are no significant differences between the LANL data file and the UN data file.

The input parameters described above were input into the CAP–88 model to generate the estimated radionuclide concentrations and resulting radiation dose equivalents. Various receptors were modeled as bounding estimates. These receptors are discussed individually below.

B.1.1.5 *Facility-Specific Maximally Exposed Individual Doses*

CAP–88 runs were made using each modeled facility's air emissions to determine the CEDE at various locations. The results were examined, and a single point at the LANL boundary where the highest dose occurs was identified. The distance and direction to these points were determined. These points are the locations of the facility-specific MEIs. The distances and directions of all facility-specific MEIs are listed in Table B.1.1.5–1. The distances and directions for all MEIs, with respect to all modeled facilities, are presented in Table B.1.1.4–19, as noted above. The dose commitment from all facility emissions were then calculated for each FS MEI location and summed to provide the total dose at that location. The contribution from each modeled

Note: This table identifies the distance and direction from each modeled facility to each facility's MEI. These values were used as input parameters for CAP–88 model runs and to calculate the dose contribution from each modeled facility to each MEI. As an example, the LANSCE MEI is located about 4,705 feet east of TA–21. Northings and Eastings in the first two rows pertain to the MEIs; Northings and Eastings in the columns pertain to the modeled facilities.

[a] Hypothetical site at boundary of LANL and San Ildefonso Pueblo.

[b] Actual MEI in the town of White Rock.

TABLE B.1.1.5–1.—*Distance and Directions to Facility-Specific Maximally Exposed Individuals*

FACILITY	MEI DISTANCE FEET (METERS)	DIRECTION
TA–3–29 (CMR)	3,575 (1,090)	North
TA–3–66 (Sigma Building)	3,560 (1,085)	North
TA–3–102 (Machine Shops)	3,380 (1,030)	North
TA–11 (High Explosives Testing)	4,300 (1,310)	South
TA–15/36 (Firing Sites)	7,415 (2,260)	Northeast
TA–16 (WETF)	2,885 (880)	South-Southeast
TA–18 (Pajarito Site: LACEF)	2,820 (860)	Northeast
TA–21 (TSTA and TSFF)	1,050 (320)	North
TA–48 (Radiochemistry Laboratory)	2,920 (890)	North-Northeast
TA–53 (LANSCE)	2,625 (800)	North-Northeast
TA–54 (Area G)	1,195 (365)	Northeast—LANL Boundary
	5,330 (1,625)	Southeast—White Rock
TA–55 (Plutonium Facility)	3,690 (1,125)	North

Note: This table lists the facility-specific MEI location from each modeled facility. These data are also contained in Table B.1.1.4–19.

facility to each MEI was calculated for each of the four SWEIS alternatives.

The MEI locations do not necessarily represent actual residences or individuals. They are merely points at the LANL boundary where the highest potential dose occurs. Some points at the LANL boundary do have residences close to them. This is especially true for those TAs located in the northern part of the LANL site, such as TA–3 and TA–53.

Two FS MEI locations were considered for Area G because it borders San Ildefonso Pueblo land. The first location is at the LANL boundary, 1,197 feet (365 meters) northeast of Area G next to San Ildefonso land. No one currently lives in that location. The second location is in the town of White Rock, approximately 5,331 feet (1,625 meters) southeast of Area G.

Some modeled facilities share the same MEI location. TA–3–29 (CMR) and TA–3–66 (Sigma) share the same MEI location, as do TA–48 (Radiochemistry Facility) and TA–55 (Plutonium Facility).

B.1.1.6 *LANL Site-Wide Maximally Exposed Individual Dose*

The LANL site-wide MEI dose was determined by examining the total dose to each FS MEI. The FS MEI with the highest total dose is considered to be the LANL site-wide MEI for that alternative. For every FS MEI location, the total dose is the dose contributed by that specific facility, plus any doses contributed by other modeled facilities.

B.1.1.7 *Population Dose*

The dose to the population living within a 50-mile (80-kilometer) radius from LANL was calculated by CAP–88 using the UN population data prepared from BBER data (BBER 1995). For each modeled facility, a population run was made for each of the four alternatives. The results from each modeled facility for each alternative were added to obtain the total population dose for that alternative.

B.1.1.8 *Isodose Maps*

Isodose maps (maps showing lines of equal dose) were generated for the region within a 50-mile (80-kilometer) radius from LANL. The isodose maps show contour lines representing the annual individual dose at the points where the lines pass through. Four CAP–88 runs were made for each emission source for each alternative in order to generate data points sufficient to create the isodose maps. The following distances (in meters) were introduced as an input to CAP–88 runs to generate these maps:

- *Run No. 1*—300, 400, 500, 600, 700, 800, 900, 1,000, 1,100, 1,200, 1,300, 1,400, 1,500, 1,600, 1,800, 2,000, 2,200, 2,400, 2,600, and 2,800
- *Run No. 2*—3,000, 3,200, 3,400, 3,600, 3,800, 4,000, 4,200, 4,400, 4,600, 4,800, 5,000, 5,500, 6,000, 6,500, 7,000, 7,500, 8,000, 8,500, 9,000, and 9,500
- *Run No. 3*—10,000, 11,000, 12,000, 13,000, 14,000, 15,000, 16,000, 17,000, 18,000, 19,000, 20,000, 22,000, 24,000, 26,000, 28,000, 30,000, 32,000, 34,000, 36,000, and 38,000
- *Run No. 4*—40,000, 42,000, 44,000, 46,000, 48,000, 50,000, 52,000, 54,000, 56,000, 58,000, 60,000, 62,000, 64,000, 66,000, 68,000, 70,000, 72,500, 75,000, 77,500, and 80,000

Dose calculations were made at each distance in 16 directions around the emission source for each alternative. The results were then used to generate the isodose maps using GIS overlays. The results of the runs for all emission sources were summed to obtain the isodose maps for all of LANL operations. Two sets of isodose maps were generated. The first set of four maps (one map per alternative) covers the region around LANL with an average individual dose higher than 1 millirem per year. The second set of four maps (one map per alternative) covers the rest of the 50-mile (80-kilometer) region where average individual doses were less than 1 millirem per year.

B.1.2 Results of Consequence Analyses

B.1.2.1 *Doses to Facility-Specific Maximally Exposed Individuals*

For each FS MEI, the total dose at the MEI location was calculated by adding the contributions from each modeled facility. The highest dose for an alternative is the LANL MEI for that alternative.

The contribution of each modeled facility to the FS MEIs for the four SWEIS alternatives are included in Tables B.1.2.1–1 through B.1.2.1–4. The totals shown on these tables are summarized in Table B.1.2.1–5.

B.1.2.2 *Dose to the LANL Site-Wide Maximally Exposed Individual*

As noted above, the LANL site-wide MEI is determined by identifying the FS MEI with the highest total dose. The location of and modeled dose to the LANL site-wide MEI for each alternative is summarized in Table B.1.2.2–1.

The NESHAP requires that the dose resulting from air emissions to the LANL MEI not exceed 10 millirem per year. As shown in Table B.1.2.2–1, this regulatory limit would not be exceeded under any of the SWEIS alternatives. In fact, the highest MEI dose was 5.44 millirem per year for the Expanded Operations Alternative, which is 54.4 percent of the

TABLE B.1.2.1–1.—*Doses to Facility-Specific MEIs from LANL Operations for the No Action Alternative (millirems per year)*

NESHAP = National Emissions Standards for Hazardous Air Pollutants (40 CFR 61, Subpart H).

regulatory limit. The LANL MEI is the LANSCE FS MEI under all alternatives.

B.1.2.3 *Collective Population Dose*

The collective dose to the population living within a 50-mile (80-kilometer) radius from LANL has been calculated for emissions from all modeled facilities. The population doses from each source for all four alternatives are presented in Table B.1.2.3–1, while the total collective population doses for the four SWEIS alternatives are presented in Table B.1.2.3–2.

An examination of Table B.1.2.3–1 reveals that most of the population dose comes from emissions from the Firing Sites. The Firing Sites emit long-lived uranium isotopes that can travel long distances without any significant decay. The emissions from LANSCE are mainly short-lived activation products that decay away in a matter of minutes or even seconds. Thus, the LANSCE emissions are important contributors to doses to individuals near LANL, but these emissions are less important to the doses for individuals farther away from LANL.

TABLE B.1.2.3–1.—*Collective Population Dose to Residents Within a 50-mile Radius from LANL (person-rem/year)*

Total[a]	13.59	33.09	10.83	13.79

[a] The values reported for population doses for this alternative, as well as the other alternatives, is higher than has been reported in the recent Annual Environmental Reports. It is important to recognize that the alternatives analyzed represent increased operations when compared to recent history. The material throughput at the different facilities under the various alternatives is presented in section 3.6.

No Action	13.59
Expanded Operations	33.09
Reduced Operations	10.83
Greener	13.79

B.1.2.4 *Isodose Maps*

Individual doses have been calculated for people living within a 50-mile (80-kilometer) radius from LANL. The highest individual dose for an alternative is the dose given to the LANL site-wide MEI for that alternative. For the 50-mile (80-kilometer) region, an individual's doses are shown on the isodose maps in Figures B.1.2.4–1 through B.1.2.4–8. Figures B.1.2.4–1 through B.1.2.4–4 show doses that are more than 1 millirem per year for each of the four alternatives. Only lines that represent a dose larger than 1 millirem per year and extend (at least in part) outside the LANL boundary are shown on the isodose maps. Figures B.1.2.4–5 through B.1.2.4–8 show doses that are less than 1 millirem per year for each alternative. To estimate their doses, individuals need only find their locations on the isodose map and identify the bounding doses nearest that location. A dose of 1 millirem per year is not considered significant

B.1.2.5 *Uncertainties*

There are many factors that introduce uncertainties into the process of projecting future doses to the public from radioactive air emissions from LANL. Some of these factors are listed below.

- The radionuclide emission rates estimated by each modeled facility are based on current knowledge regarding future operations at the facility. However, the level of funding, exact activities, and exact conditions associated with future operations cannot be predicted with certainty. Therefore, the emission rate estimates cannot be viewed as accurate or precise values.
- The LANL site-wide MEI dose is sensitive to the assumptions and operations associated with LANSCE. Procedures are in place to monitor the modeled MEI dose and ensure that the 10 millirem per year limit is not exceeded. Population doses, on the other hand, are more sensitive to the assumptions and operations associated with the Firing Sites. For example, a 25 percent change in uranium use (which is assumed to mean a 25 percent change in uranium emissions) would change the population dose by about 20 percent.
- The parameters introduced into the CAP–88 model cannot be exact, especially the meteorological data. The average meteorology for a 3-year period was used in the modeling, which is a reasonable and good prediction for future years. However, any single, future year could be anomalous, resulting in a collective dose estimate different from that presented in this report. Again, active monitoring and control of atmospheric releases is conducted to ensure that the public dose limits are not exceeded.
- The modeled dose is also very sensitive to the assumed period of exposure. For the purposes of this analysis, the very conservative assumption is made that the MEI is a person who stays in the same location 24 hours a day, 365 days a year. Furthermore, it is assumed that this person is not shielded from the emissions by clothing or shelter (e.g., a building, auto, home, etc.).
- The area source term for TA–54 was calculated from AIRNET monitoring data.

There are uncertainties in those data for tritium in its water vapor form due to a recent discovery that the silica gel samplers are not collecting water with a high efficiency. It is estimated that the underestimation, which is being quantified, will represent only a very small addition to the collective population dose and LANL MEI doses.

B.2 NONRADIOLOGICAL AIR QUALITY

The methodology description and the analysis results presented in chapter 5 are supplemented in this appendix with details on each aspect of modeling and analysis for criteria pollutants and toxic chemical emissions.

B.2.1 Assumptions, Data Sources, Standards, and Models

B.2.1.1 *Applicable Guidelines/ Standards and Emission Sources*

Criteria Pollutants

The *Clean Air Act* mandates that the EPA establish primary and secondary National Ambient Air Quality Standards (NAAQS) for pollutants of concern nationwide. These pollutants, known as criteria pollutants, are carbon monoxide, sulfur dioxide, nitrogen dioxide, ozone, lead, and particulate matter smaller than 10 microns in aerodynamic size (PM_{10}). As of September 16, 1997, in addition to the PM_{10} NAAQS, a new NAAQS became effective for particulate matter equal to or less than 2.5 microns (micrometers) in aerodynamic diameter ($PM_{2.5}$). These new standards will not require imposition of local area controls until 2005, and compliance determinations will not be required until 2008. Additionally, EPA revised the NAAQS and associated reference method for determining ozone attainment on July 18, 1997. This standard also will be applicable to LANL.

The State of New Mexico also has established ambient air quality standards for carbon monoxide, sulfur dioxide, total suspended particulates, hydrogen sulfide, and total reduced sulfur (New Mexico Administrative Code [NMAC], Title 20, Chapter 2, Part 3). State of New Mexico ambient air quality standards are more restrictive than the national standards and are listed in attachment 1.

Criteria pollutants released into the atmosphere from LANL operations are emitted primarily from combustion facilities such as boilers, emergency generators, and motor vehicles.

Toxic Air Pollutants

Chemicals are currently used at LANL in separately located groups of operations or laboratory complexes (TAs) that are spread out over a large geographic area (43 square miles [11,140 hectares]). Toxic air pollutants from these TAs may be released into the atmosphere from many different ongoing activities, including laboratory, maintenance, and waste management operations. Two types of toxic air pollutants are considered in this analysis: noncarcinogenic and carcinogenic.

The two database information systems used primarily in this analysis are the 1995 Automatic Chemical Inventory System (ACIS) (LANL 1995a) purchase data and the Regulated Air Pollutants (RAP) Report data (LANL 1990).

ACIS is a listing of chemicals purchased at each LANL facility in each calendar year. The 1995 ACIS list identified more than 2,000 chemicals. This list was reduced to 382 chemicals by eliminating from consideration those that do not have adequate vapor pressure in a liquid state to be evaporated during chemical operations or have very low toxicity. Fifty-one of these 382 chemicals are considered by EPA to be carcinogenic. For the purpose of this analysis, it was assumed that air emissions could result from the use of any of the 382 chemicals from any of the 30 separate TAs that purchased these chemicals. A list of these chemicals is provided in attachment 2.

RAP is a LANL site-wide nonradiological air emissions inventory that was conducted at LANL in 1990. This inventory, however, was prepared more than 7 years ago when LANL operations were significantly different from current operations. Because these data are not current, RAPS information was used in this analysis only to supplement ACIS data and other information gathered for this study.

Noncarcinogens. *Short-Term Guideline Values.* While no national or State of New Mexico standards have been established for noncarcinogens, the New Mexico Environment Department (NMED) has developed guideline values (GVs) for determining whether a new or modified source emitting a toxic air pollutant would be issued a construction permit (NMED/AQCRs, revised November 17, 1994). These GVs are 8-hour concentrations that are 1/100 of the Occupational Exposure Limits (OELs) established by the American Conference of Governmental Industrial Hygienists (ACGIH 1997) or the National Institute of Occupational Safety and Health (NIOSH). The State of New Mexico listing was supplemented with the most current information on the lowest values for OELs from these sources. These GVs were used in this analysis in screening for potential short-term impacts of toxic releases from LANL operations.

Annual Average Guideline Values. The GVs used in this analysis are the inhalation reference concentrations (RfCs) from EPA's Integrated Risk Information System (IRIS) (EPA 1993b). RfCs are daily exposure levels to the human population (including sensitive subgroups) during a lifetime (70 years) that could occur without appreciable risk of deleterious effects.

Carcinogens. The GVs used in this analysis to estimate potential impacts of carcinogenic toxic air pollutants from LANL operations are based on an incremental cancer risk of one in a million (1.0×10^{-6}) (i.e., one person in a million would develop cancer if exposed to this concentration over a lifetime), a level of concern established in the *Clean Air Act*.

This value was used in the screening for the estimated combined incremental cancer risk associated with all of the carcinogenic pollutants emitted from LANL facilities at any location. For the purpose of screening individual carcinogens, a cancer risk of 1.0×10^{-8} was established as the GV.

B.2.1.2 *Receptors and Receptor Sets*

Two sets of receptors (i.e., locations where air quality levels were estimated) were considered for the analyses of criteria and toxic air pollutants.

- The first set of receptors includes nearby identified actual locations of human activity that might be affected from the emissions from LANL facilities. These include: (1) schools, hospitals, parks and playgrounds within Los Alamos; (2) residences (including those in trailer parks) in all directions surrounding all of LANL facilities in Los Alamos County; and (3) towns, cities, and sensitive national and cultural areas within approximately 50 miles (80 kilometers) of LANL. These receptors, which are listed in attachment 3, are referred to as sensitive receptors.
- The second set of receptors includes all of the closest off-site (i.e., fence line) locations (in 10-degree increments) around each TA to which the public could have access. These receptors are referred to as fence line receptors.

The potential impacts of air pollutants on workers employed at the LANL facilities were not considered as part of this analysis. Different regulations apply to an occupational setting, and the controlled nature of the work, along with surveillance systems associated with these controls, restricts routine exposures for workers. This analysis is focused on exposure to the public, and is based on a methodology that initially assumes that chemicals that are purchased are entirely available for release to the atmosphere outside the facility in which the chemicals are used.

Air quality standards have been established by the State of New Mexico for criteria pollutants for both short-term (i.e., 1-hour, 3-hour, 8-hour, and 24-hour) and long-term (e.g., 30-day, quarterly, and annual) time periods. In addition, GVs also were developed for toxic pollutants for both short-term (8-hour) and long-term (annual) time periods. Using these standards and GVs, the potential impacts of the pollutant emissions from LANL operations on these receptor sets were analyzed as discussed in the following paragraphs.

Criteria Pollutants

Short-term and long-term impacts for CO, NO_2, and SO_2, TSP, PM_{10}, and lead were estimated at the sensitive receptors, and the results were compared with applicable air quality standards. Both time frames were analyzed to address the potential short-term (acute) and long-term (chronic) impacts of these pollutants at locations where the public could have both short-term and long-term exposure to emissions from LANL facilities. Hydrogen sulfide and total reduced sulfur emissions are associated mostly with oil and gas industry; therefore, analysis for these pollutants was not necessary at LANL.

Short-term impacts also were analyzed at the fence line receptors surrounding TA–3, TA–16, and TA–21 in order to account for potential short-term exposure near the locations with relatively large combustion sources. The combustion sources at the other TAs are minor (primarily small boiler units and emergency generators) relative to the larger combustion units found at TA–3, TA–16, and TA–21, and are mostly for emergency back-up. The potential impacts at the fence line receptors of these minor sources were not considered.

Toxic Air Pollutants

Noncarcinogens. The potential short-term (acute) and long-term (chronic) impacts of these pollutants at locations where the public could have both short-term and long-term exposure to emissions from LANL facilities were considered.

Short-term impacts were analyzed at the fence line receptors. Long-term impacts were not considered at these receptors because, although it is possible that the public could have access to fence line areas for short periods of time, the fence line locations are not places where visitors can freely walk around, nor is pedestrian traffic at these locations encouraged or actually encountered on a regular (long-term) basis.

Carcinogens. The annual impacts from the emissions of carcinogenic toxic air pollutants were analyzed at the sensitive receptors. Although GVs for short-term exposure were used in the screening steps, the more meaningful comparisons were to long-term GVs for sensitive receptors.

B.2.1.3 *Air Quality Dispersion Models*

The EPA's Industrial Source Complex Air Quality Dispersion Model (ISC–3) was used for both the criteria and toxic pollutant analyses. ISC–3 is a versatile model that is often used to predict pollutant concentrations from continuous point, area, volume, and open disposal cell sources (EPA 1992b). This versatile model is often preferred by the EPA because of the many features that enable the user to estimate concentrations from nearly any type of source emitting nonreactive pollutants.

EPA's PUFF model was used for a screening level analysis of emissions from LANL's High Explosives Firing Sites (HEFSs) at TA–14, TA–15, TA–36, TA–39, and TA–40. The PUFF model is designed to estimate downwind concentrations from instantaneous releases of pollutants (EPA 1992d).

The HOTSPOT code was used in combination with the ISC–3 model for a detailed analysis of emissions from HEFF in order to provide a more readily usable input data file to the health effects analysis used in this SWEIS than provided by PUFF. The HOTSPOT code is designed for detonation of high explosives, and was used specifically to provide input data to the ISC–3 model (ORNL-LLNL 1996).

B.2.2 Criteria Pollutants—General Approach

The combustion sources that were evaluated in the analysis of criteria pollutants are listed in attachment 1. An atmospheric dispersion modeling analysis was conducted to estimate the combined potential air quality impacts of the emissions from each of these emission sources.

No quantitative analysis of vehicular-related emissions was performed as part of this analysis, but this emission source was included in the assumed background. Although the project alternatives may have different effects on the travel patterns in the study area as a result of changes in the number of LANL employees who would commute to Los Alamos, the future population of Los Alamos is expected to be the same under all of the alternatives. Therefore, the change in regional emissions under any of the future project alternatives are not expected to be more than a few (less than 5) percent. Because the study area is in attainment for the pollutants that are released primarily from motor vehicles (carbon monoxide and ozone precursors and nitrogen oxides [NO_x]) and because there are no nearby heavily congested traffic areas or major sources or ozone precursors (i.e., hydrocarbons and nitrogen oxides), no potentially significant air quality impacts are expected from the project alternatives.

B.2.2.1 *Criteria Pollutants—Methodology*

The analysis of combustion-related pollutants used standard analytical modeling techniques based on atmospheric dispersion modeling and emissions estimated under peak and actual annual average operating conditions of each major combustion unit. This information, together with stack locations and exhaust parameters (i.e., heights, diameters, flow rates), was available from LANL's air quality permit applications. Estimates of future emission rates were based on the operations anticipated under the Expanded Operations Alternative—the worst-case alternative with respect to emission rates from the combustion sources. These emissions were modeled using the ISC–3 model and meteorological data collected at TA–6. The methodology and procedures used are provided in attachment 1.

B.2.2.2 *Results of Criteria Pollutant Analysis*

The results of the analysis of criteria pollutants from LANL's combustion sources are presented in attachment 1. As shown, the highest estimated concentration of each pollutant is below the appropriate ambient air quality standard. None of the project alternatives, therefore, are predicted to significantly impact criteria pollutant levels.

B.2.3 Toxic Air Pollutants—General Approach

Unlike a production facility with well-defined operational processes and schedules, LANL is a research and development facility with great fluctuations in both the types of chemicals emitted and their emission rates. Because LANL's toxic air pollutant emission rates are relatively low (compared to releases from production facilities), vary greatly, are released from hundreds of sources spread out over a large geographic area, and are well below the state's permitting threshold limits, toxic air pollutant emissions are not monitored. Current emission rates and stack parameter information necessary to conduct a conventional air quality analysis of the releases of toxic air pollutants are therefore not available.

An alternative approach was developed specifically for this analysis to estimate the potential air quality impacts of these pollutants. This approach is based on the use of screening level emission values (SLEVs). SLEVs are conservatively estimated hypothetical emission rates for each of the toxic air pollutants that could potentially be emitted from each of LANL's TAs and that would not result in air quality levels harmful to human health under current or future conditions. These SLEVs were compared with conservatively estimated pollutant emission rates on a TA-by-TA basis to determine potential air quality impacts of toxic air pollutants from LANL operations. This process consisted of the following steps:

- From over 2,000 chemical compounds listed as being used at LANL, 382 toxic air pollutants (including 51 carcinogens) were selected for consideration based on chemical properties, volatility, and toxicity.
- A methodology based on SLEVs was used to estimate the potential worst-case impacts of the toxic air pollutants. SLEVs for each chemical for each TA were compared with emission rates conservatively estimated from chemical use rates. If a conservatively estimated emission rate for a given pollutant from a given TA was less than SLEV, that pollutant emission source was deemed not to have the potential to cause significant air quality impacts, and, as such, no detailed analyses was required; if SLEV was less than the estimated emission rate for a given pollutant from a given TA, a more detailed analysis was conducted.
- An additive impact analysis was conducted to estimate the potential total impact from the emissions of each pollutant from more than one TA and the total incremental cancer risk from all of the carcinogenic pollutants combined at any of the sensitive receptor locations considered.

The methodology used in this analysis followed modeling guidelines for toxic pollutants established by the EPA (EPA 1988, EPA 1992c, EPA 1992e, and EPA 1992f) in that it first uses screening level evaluations based on conservative assumptions and resulting in maximum potential impacts, followed by more detailed analyses based on more realistic assumptions. The overall procedure used for this air quality assessment, including the development of SLEVs, is summarized in Figures B.2.3–1 and B.2.3–2. Also shown on these figures are the procedures used to compare SLEVs with the available emission data and the steps taken to evaluate the pollutants with potentially significant impacts. Each pollutant with the potentially significant impacts (as a result of the screening-level analyses) was subjected to progressively more detailed and more realistic evaluations.

B.2.3.1 *Toxic Pollutants—Methodology for Individual Pollutants*

Screening Level Analysis

Once SLEVs (both short-term and long-term) were established for each of the toxic air pollutants on a TA-specific basis (attachment 4, Methodology), a comparison was made between these values and conservatively estimated emission rates based on the Expanded Operations Alternative. A ratio was developed for each chemical by dividing the SLEV by the estimated emission rate (SLEV/Q).

These results, in the form of worksheets (an example for TA–3 is provided in attachment 5),

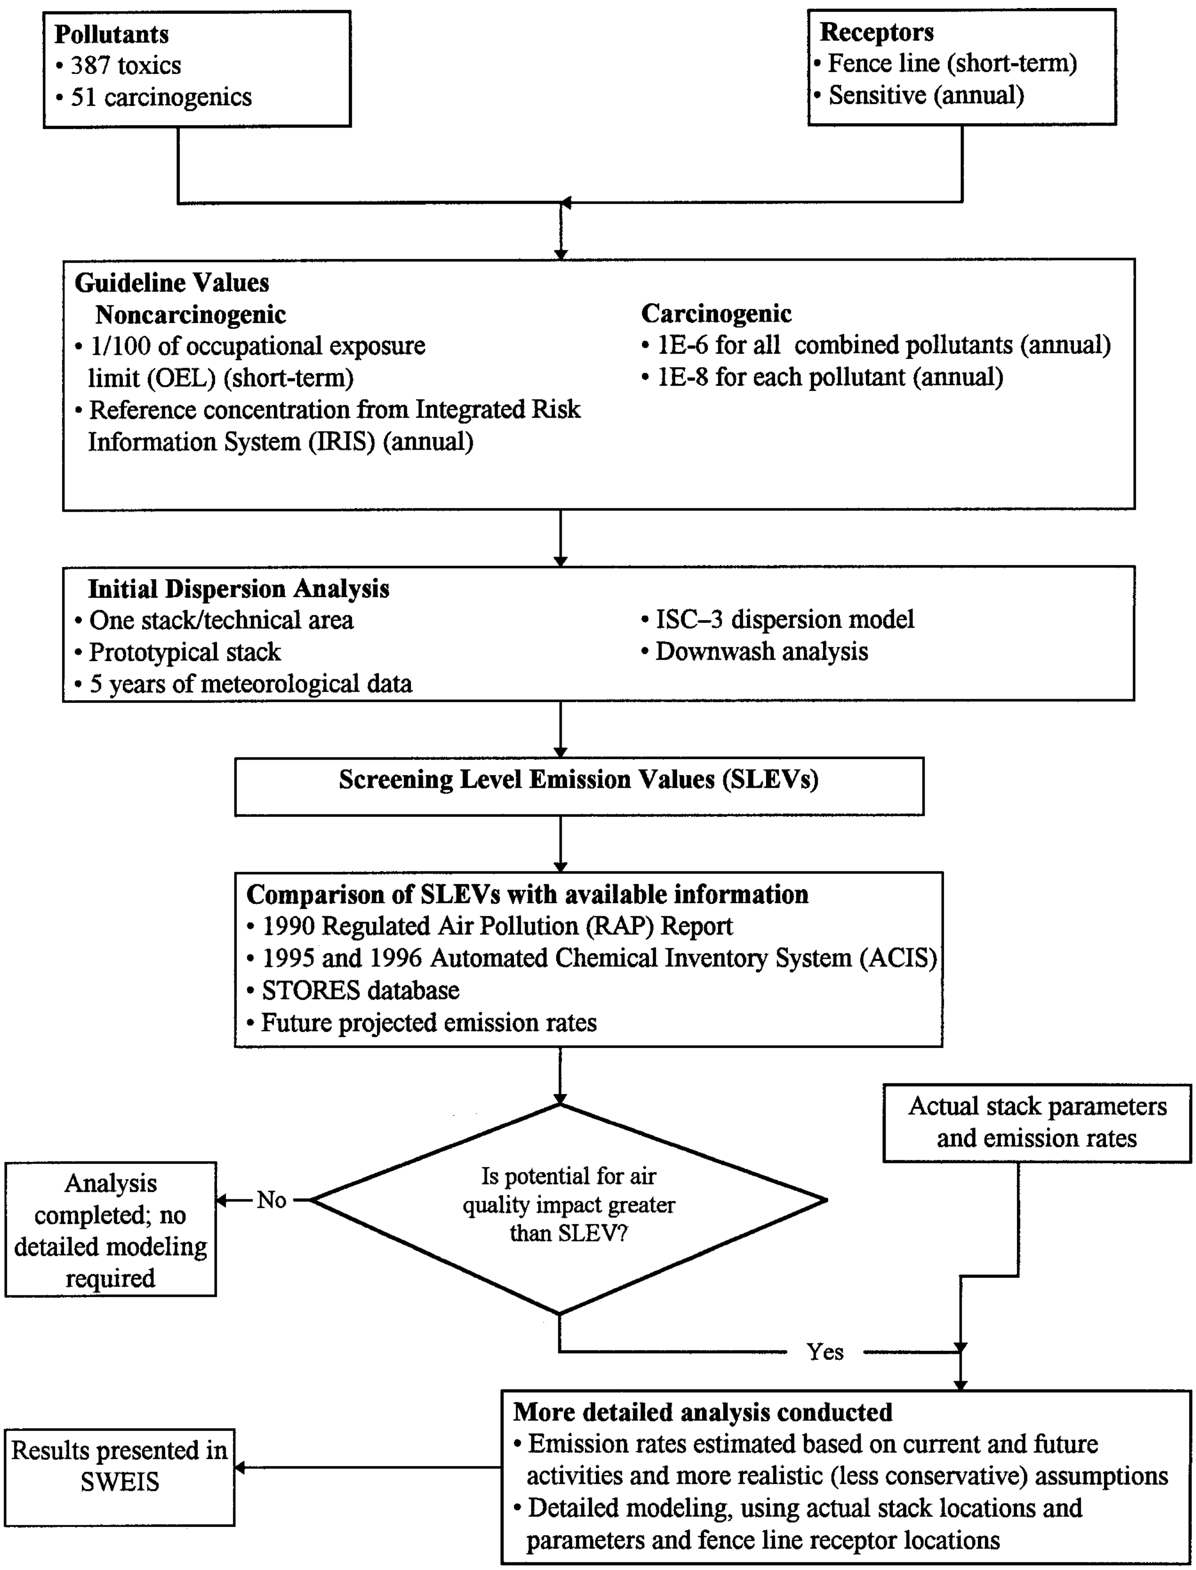

FIGURE B.2.3–1.—*Process Used for Evaluating Toxic Air Pollutants.*

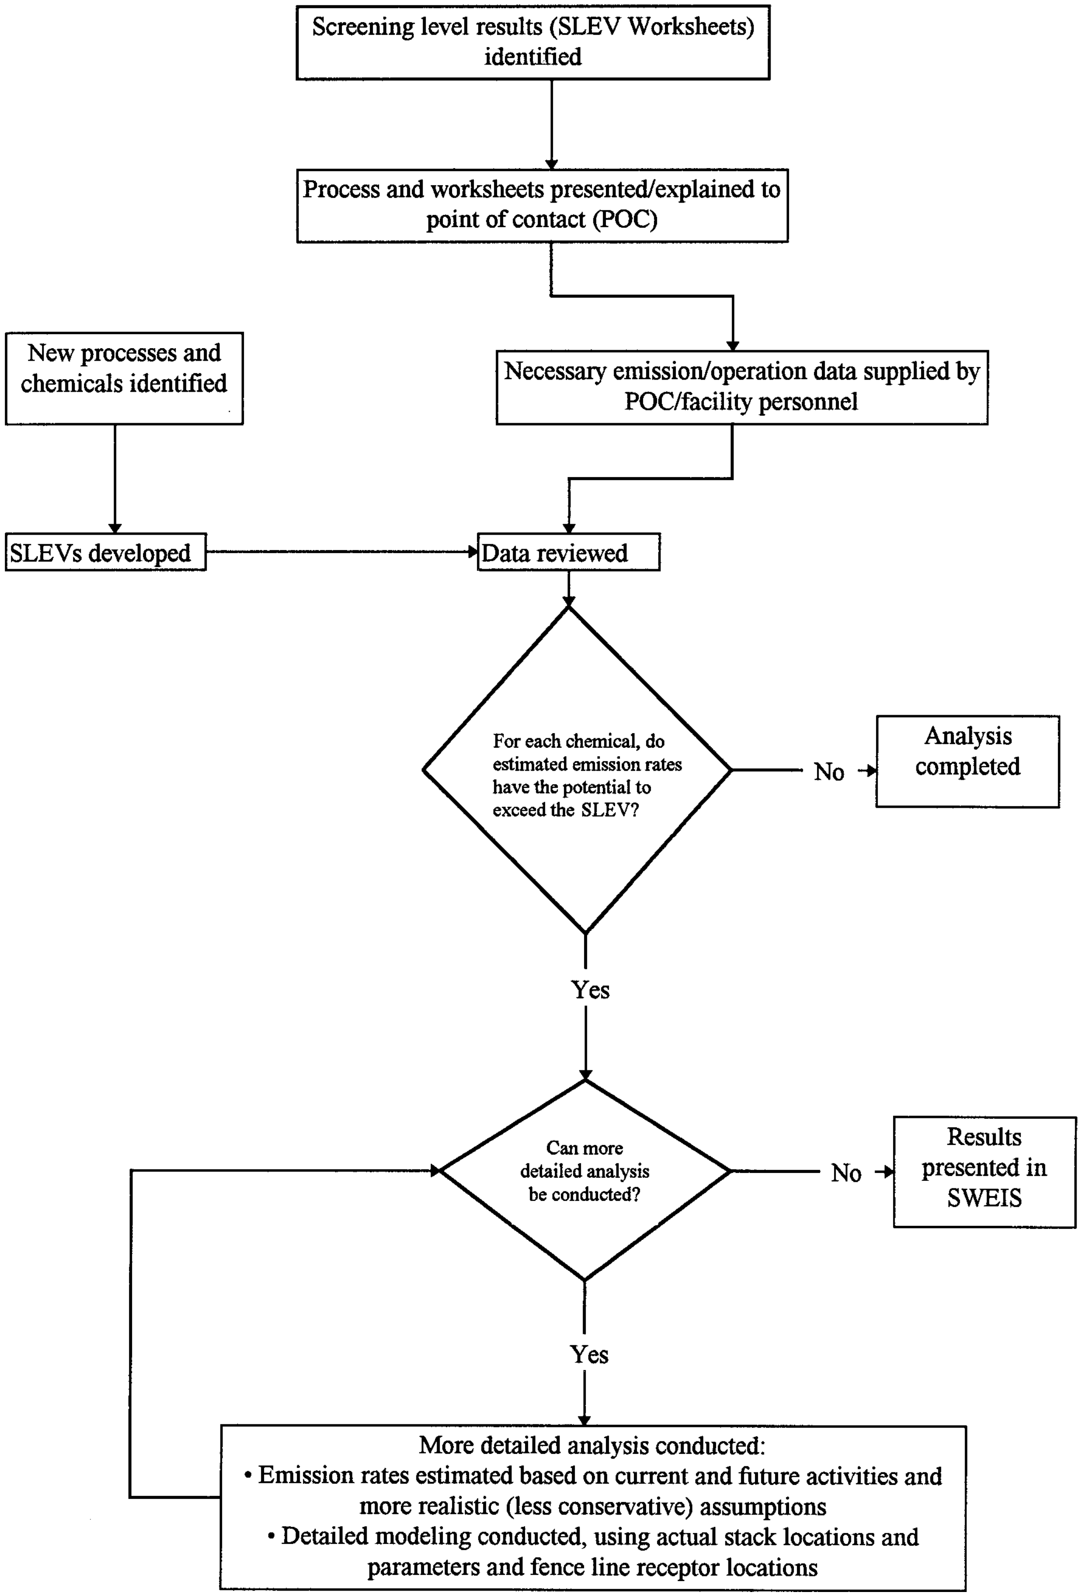

FIGURE B.2.3–2.—*Procedures for Evaluating Potential Impacts of Toxic Air Pollutant Emissions from Each Technical Area.*

were presented to knowledgeable site personnel who are aware of the activities and processes that are currently occurring at each TA as well as those that might occur in the future. In order to streamline the process, the relationship between SLEVs and the estimated emission rates for each TA were presented in two data sets.

The first data set included those chemicals with SLEV/Q ratios greater than 100. For each of these chemicals, a determination was made as to whether the utilization of that chemical would increase by more than one hundred times under future operation(s) of LANL under any of the project alternatives considered. Essentially, this meant that for each TA a determination had to be made as to whether the utilization of a chemical would increase over current use rates by a factor of 100. If a determination could be made that the future use of that chemical would not increase by this factor, no further evaluation of that chemical was required. If such a determination was not possible, a more detailed analysis was conducted.

The second data set included all the chemicals with a SLEV/Q ratio less than 100, and included those chemicals with a SLEV/Q ratio greater than 1 but less than 100, as well as those chemicals with a ratio less than 1. For each chemical with a ratio greater than 1 but less than 100, an evaluation was made as to whether the estimated emissions under any of the future alternatives would exceed the SLEV. Essentially, this meant that for each TA a determination had to be made as to whether the utilization of that chemical would increase over current use rates by a factor greater than the SLEV/Q ratio. If a determination could be made that the future use of that chemical would not increase by this factor, no further evaluation of that chemical was required. If such a determination was not possible, a more detailed analysis was conducted. For those chemicals with a SLEV/Q ratio less than 1 (i.e., SLEVs were potentially being exceeded under current conditions), more detailed analyses were conducted.

Two exceptions to the details associated with this approach were made. Information on the TAs for high explosives operations were derived using a model more appropriate for screening short-term exposure concentrations under those conditions (attachment 13). The second involved screening the emissions of chemicals from The Health Research Laboratory (HRL) at TA–43. Because of the proximity of HRL to actual receptors, all analyses for carcinogens as well as noncarcinogens were performed for actual receptors rather than fence line receptors (attachment 14).

Detailed Analysis

The detailed air quality analysis consisted of one or both of the following steps:

- Development of emission rates and source terms parameters using actual process knowledge
- Dispersion modeling using actual stack parameters and receptor locations

Two consequences may result from the detailed analysis for each chemical from each TA: (1) either there is no potential to contravene a GV (in which case no additional analyses were required), or (2) there is a potential to contravene a GV (in which case additional analyses were required). A pollutant with the potential to contravene a GV was subject to evaluation in the health and ecological risk assessment process for this SWEIS.

B.2.3.2 *Results of the Toxic Pollutant Analysis—Individual Pollutants*

Screening Level

The first data set considered those chemicals with SLEV/Q ratios greater than 100. For more than 90 percent of the toxic air pollutants, a determination was made (based on current and proposed operations of the TAs) that the utilization of these chemicals would not increase by more than 100 times under any of the project alternatives. The second data set included chemicals with SLEV/Q ratios greater than 1 but less than 100, and ratios less than 1. A determination was made as to whether the utilization of that chemical would increase over current use rates by a factor greater than the SLEV/Q ratio. The list of carcinogens also was reduced from 51 to 35 because some of the chemicals are no longer used and are not projected for future use. Based on worksheets for the chemicals in these data sets, and information on potential future use, operations at 13 locations were identified with the potential to exceed a GV.

Detailed Analysis

Detailed analyses were conducted for the following emission sources:

- Methylene chloride emissions at TA–3 (attachment 7)
- Beryllium emissions at TA–3 (attachment 8)
- Nickel dust emissions at TA–3 (attachment 9)
- Paint booth (primarily volatile organic compound) emissions at TA–3 and TA–60 (attachment 10)
- Incinerator emissions (primarily metals and volatile organics) at TA–16 (attachment 11)
- Emissions (primarily volatile organic compounds) from open burning operations at the High Explosives Treatment and Disposal Facility at TA–16 (attachment 12)
- Emissions (primarily metals) from High Explosives Firing Site (HEFS) operations at TA–14, TA–15, TA–36, TA–39, and TA–40 (attachment 13)
- Emissions (primarily volatile organic compounds) from the Health Research Laboratory at TA–43 (attachment 14)
- Chloroform emissions at TA–53 (attachment 15)
- Beryllium emissions at TA–55 (attachment 16)
- Nitric and hydrochloric acid emissions at TA–55 (attachment 17)
- Nitric and hydrochloric acid emissions at TA–59 (attachment 18)
- Ozone Emissions at TA–53 (attachment 19)

Detailed Analyses—Results

Emissions from two sources were referred to the health and ecological risk analysis process. The analysis for TA–43 showed the potential to exceed the GVs for four chemical carcinogens from HRL: chloroform, trichloroethylene, formaldehyde, and acrylamide.

The detailed analysis for HEFF indicated that the same chemicals that had the potential to exceed a GV in the previous screening step, would also have the potential to exceed their respective GVs using somewhat different parameters and a different model than used in the screening analysis. A different model was used in the detailed analysis in order to provide output data in a form more readily usable for the health risk analysis. Additional information on the following chemicals was referred to the health and ecological risk assessment process for this SWEIS:

- Depleted uranium, beryllium, and lead from TA–15
- Depleted uranium, beryllium, and lead from TA–36

- Beryllium and lead from TA–39
- Depleted uranium and lead from TA–14

B.2.3.3 *Toxic Pollutants—Methodology for Combined Impacts Analyses*

The following analyses were conducted to ensure that the combined effects from the releases of all of the chemicals from all the TAs would not exceed the GVs.

Noncarcinogens

An analysis of potential short-term impacts at a TA's fence line receptors showed that the 8-hour impacts from the releases of that TA were significantly greater (i.e., more than two orders of magnitude) than the impacts from the releases of a nearby TA. This is because the TAs are relatively far apart in comparison to the distances between the emission sources of a TA and its fence line receptors. Therefore, it is unlikely that the additive short-term impacts of noncarcinogenic pollutants at the fence line receptors of a TA would be significantly different from the maximum concentrations previously estimated for that TA.

An analysis of annual potential impacts at sensitive receptors showed that these impacts were significantly less (i.e., less then two orders of magnitude) relative to the appropriate GVs than the corresponding short-term impacts at the fence line receptors. Therefore, it is unlikely that the additive annual impacts of the noncarcinogenic pollutants at the sensitive receptors would be significant.

Carcinogens

Two different versions of additive impacts for carcinogens are presented. Both consider impacts at sensitive receptors based on annual ambient concentrations of pollutants. Short-term additive impacts for carcinogens at fence line receptors were not considered for the same reasons as for noncarcinogens. However, long-term impacts at sensitive receptors were considered because EPA considers in their standard setting process that risk from carcinogens can be additive for all carcinogenic chemicals.

The first version considered whether emissions of the same chemical from all TAs (whether of not it was actually used at that TA), at the SLEV rate (whether or not that maximum rate was actually projected at that TA) would exceed the total guideline risk value of 1×10^{-6}. The risk due to exposure at the maximum concentration over a lifetime for any receptor for each of the TAs was added to the separately calculated maximum concentration for any receptor for each of the other TAs, regardless of whether the same receptor was indicated.

The second version modeled simultaneous emissions of the same chemical at actual projected rates for each of the TAs, and recorded the maximum concentration at any receptor location. The risk due to exposure at that concentration over a lifetime was then added to the risks calculated in a similar fashion for each of the other chemicals. Risks were added regardless of whether or not the same receptor was involved. That total risk was also compared to the guideline risk value of 1×10^{-6} of any excess cancer from a lifetime of exposure.

B.2.3.4 *Toxic Pollutants—Results of Combined Impact Analysis*

Releases of Each Carcinogenic Pollutant from All TAs

The estimated combined cancer risk associated with releases of each of these pollutants from all TAs is 1.23×10^{-7}, which is below the GV of 1.0×10^{-6}. As such, no potentially significant air quality impacts were estimated.

Releases of All Carcinogenic Pollutants from All TAs

Results of this analysis are presented in attachment 6. As shown, the potential combined incremental cancer risk associated with releases of all carcinogenic pollutants from all TAs is slightly above the GV of 1.0 x 10^{-6}.

The major contributors to the estimated combined cancer risk values are chloroform, formaldehyde, and trichloethylene from HRL at TA–43 and multiple sources for methylene chloride. The estimated maximum cancer risk for each of these individual pollutants is 8.74 x 10^{-7}, 5.17 x 10^{-8}, 6.73 x 10^{-8}, and 6.84 x 10^{-8}, respectively. Of these, the relative contribution of chloroform emissions alone to the combined cancer risk value is more than 87 percent. The impacts of TA–43 emissions are due to a combination of relatively high emission rates, close proximity between receptors and sources, and the elevation of the receptors.

Because the result of this analysis was slightly above the specified GV of 1.0 x 10^{-6} and a simplifying but conservative approach was used that added the maximum risk from each chemical even though different receptors may have been involved, a more detailed analysis that considered the impact at each specific receptor location was conducted. This more refined analysis estimated the combined cancer risk at each of the 180 sensitive receptor locations.

As shown in attachment 6, the combined incremental cancer risks associated with releases of all carcinogenic pollutants from all TAs at the receptor locations where these impacts actually occur are slightly above the GV of 1.0 x 10^{-6} at the two locations within the LANL medical center: 1.17 x 10^{-6} at a receptor in an air intake duct and 1.07 x 10^{-6} at an operable window. Because the estimated cancer risk at these two receptor locations is slightly above the GV of 1.0 x 10^{-6}, these results were referred to the health and ecological risk assessment processes for this SWEIS.

ATTACHMENT 1
ANALYSIS OF CRITERIA POLLUTANTS FROM COMBUSTION SOURCES

Technical Areas: TA–3, TA–8, TA–15, TA–16, TA–18, TA–21, TA–22, TA–33, TA–35, TA–39, TA–41, TA–43, TA–46, TA–48, TA–49, TA–50, TA–53, TA–54, TA–55, TA–58, TA–59, TA–61, TA–63, and TA–64.

Emission Sources

The sources of criteria pollutant emissions at LANL are mostly combustion facilities. The largest contributors are steam plants and an asphalt plant. There are also several smaller sources. The following emission sources were considered:

MAJOR SOURCES	LOCATION	FUEL
Steam Plant	TA–3–22–1	Natural gas/oil # 2
Steam Plant	TA–21–357–1	Natural gas/oil # 2
Replacement Boiler	TA–16–4	Natural gas
Replacement Boiler	TA–16–5	Natural gas
Replacement Boiler	TA–16–6	Natural gas
Replacement Boiler	TA–16–13	Natural gas
Asphalt Heater	TA–3–73–2	Oil #2
Water Pump	TA–54–1013	Natural gas
Incinerator	TA–16	Solid waste/waste oil

Note:

Emissions from the following smaller combustion sources also were considered.

- 62 miscellaneous boilers located at various TAs
- 149 standby emergency generators (7 natural gas, 50 diesel, and 92 gasoline fueled)

Pollutants Considered

As required by the *Clean Air Act*, NAAQS have been established for six major air pollutants: CO, NO_2, ozone (O_3), particulate matter smaller than 10 microns (PM_{10}), SO_2, and lead (Pb). Each of these pollutants was considered.

Emission Rates

Major Assumptions

1. For the dual-fueled boilers, fuel oil emission rates were used to estimate short-term concentrations, and natural gas emission rates were used to estimate annual emission rates.

2. Emission factors were obtained from EPA's Compilation of Air Pollution Emission Factors (AP-42) (EPA 1995).

3. Peak load emission rates ($ER_{peak\ load}$) were estimated based on the capacity of each unit.

$$ER_{peak\ load} = \frac{\text{Unit Capacity / Design Capacity x Emission Factor}}{\text{Heating Value of Fuel}}$$

   See Tables A and B of this attachment.

4. Annual average emission rates (ER_{annual}) were based on the annual fuel consumption rates (assuming that a 100 percent capacity was used).

$$ER_{annual} = \text{Emission Factor x Fuel Usage}$$

   See Table C of this attachment.

5. PM_{10} emissions during the combustion of diesel and gasoline fuels or fuel oil were conservatively assumed to be half of the total suspended particulate (TSP) emissions. Particulates emitted during the combustion of natural gas are less than 1 micron (1 micrometer) in diameter; hence, for natural gas combustion, PM_{10} emissions were considered equal to TSP emissions.

6. It was conservatively assumed, as per New Mexico Air Quality Bureau's guidelines, that 40 percent of exhausted NO was converted to NO_2 when the exhaust plume reached fence line receptors a few hundred meters away from the source. Conversion to NO_2 depends on the presence of ozone in the surface atmospheric layer. It usually takes several hours for full conversion.

7. Based on the LANL information, it was assumed that emergency and standby generators operate a maximum of four continuous hours a day.

Dispersion Modeling Analysis

The EPA Industrial Source Complex model, Version 3 (ISC–3) was applied in the analysis of criteria pollutants. ISC–3 is a steady-state Gaussian dispersion model validated to be used in a short- and a long-term mode in regulatory and nonregulatory applications. The model is capable of handling multiple point sources, stack-tip downwash calculation, buoyancy-induced dispersion, as well as having an algorithm to account for the aerodynamic downwash due to the nearby buildings. The actual options that were used to analyze emissions from combustion sources are as follows:

- In the ISC–3 short-term mode:
  - Stack-tip downwash
  - Buoyancy-induced dispersion

— Final plume rise
— Calm winds processing
— Default wind profile exponents and potential temperature gradients
— Simple terrain
— Rural dispersion
— Aerodynamic downwash (where applicable)
— Constant emission rates throughout the modeling period
— No precipitation scavenging

Other assumptions include:

- All chemicals are released to the atmosphere rather than used in process or product, or sent to waste disposal or recycling after use.
- There is no time spent indoors or inside automobiles; whereas, people actually spend more than 80 percent of their time indoors. Being inside would cut the concentration by half as a minimum.

Modeling Procedures

1. TA–3, TA–21 and TA–16 boiler plants were modeled using actual emission locations and actual stack parameters, as provided by LANL. Wake effects of the boiler buildings and buildings in the immediate vicinity of the emission sources were considered.

2. The waste incinerator at TA–16, the water pump at TA–54, and the asphalt plant heaters at TA–3 were modeled using actual locations and stack parameters, as obtained from LANL. Wake effects of the incinerator building were considered.

3. The emission rates of the other combustion sources considered (i.e., small boilers and standby and emergency generators—natural gas, diesel and gasoline fueled) were summed up by TA and modeled as if their combined emissions were released from the center of the TA where they are located. The following prototypical stack and stack parameters were assumed for each of these sources.

    - Stack height: 6 meters
    - Stack diameter: 0.5 meters
    - Stack exit velocity: 9 meters per second
    - Stack temperature: 127°C

4. Impacts from combustion sources were considered for both peak and normal (annual average) operating conditions. Peak load emissions were used to estimate short-term impacts and annual average emissions were used to estimate long-term impacts.

5. Emergency and standby generators were modeled to estimate short-term impacts only.

6. Five years of Los Alamos meteorological on-site observations for years 1991 through 1995 were used in dispersion analysis. These 5 years of data were obtained by using the EPA PC RAMMET program, with surface observations and morning and afternoon mixing heights data as inputs. The

surface observations were collected at the TA–6 meteorological tower at LANL. Mixing heights data were estimated based on the Albuquerque upper air observations and Santa Fe surface data.

7. Lead emissions from incinerator and oil-fired asphalt heaters (the two combustion sources that continuously emit lead) were modeled using actual source parameters. Concentrations at the sensitive receptors were found 5 orders of magnitude lower than the NAAQS quarterly standard for lead of 1.5 micrograms per cubic meter.

8. Background concentrations were conservatively assumed to be 20 percent of the corresponding standard.

Results:

Nitrogen Dioxide Modeling Analysis for Combustion Sources at LANL

Initial modeling of NO_x concentrations resulted in a modeled 24-hour concentration of 519.76 micrograms per cubic meter (based on ISCST3 modeling). The applicable 24-hour standard, per New Mexico Ambient Air Quality Control Standards (AAQS) is 147 micrograms per cubic meters (adjusted for temperature and pressure [elevation]). Thus, based on the preliminary analysis, NO_x modeled concentrations are above the New Mexico AAQS. Therefore, the following methodology was used to evaluate the NO_2 concentrations.

New Mexico Air Quality Bureau—NO_2 Modeling Methodology. The Bureau has approved two screening techniques for estimating NO_2 concentrations from NO_x point sources. The first technique is a partial conversion rate of 40 percent, which is only applicable to 24-hour concentrations. Therefore, if the NO_x concentration is 200 micrograms per cubic meter, the NO_2 concentration can be assumed to be 80 micrograms per cubic meter. The second technique is that some sources will need to examine the atmospheric chemistry in a more rigorous manner. The guidance provides for using Ozone Limiting Method (OLM) to more accurately determine NO_2 concentrations. OLM should be used to resolve, if possible, any NO_2 standard exceedances at each receptor that shows a violation.

Modeling Analysis. Using this partial conversion rate of 40 percent, the acceptable 24-hour standard for LANL would be 368 micrograms per cubic meter [147 micrograms per cubic meter per 0.40] for NO_x. For the annual concentration analysis, no conversion was used, and the full modeled values were considered while comparing the results with the applicable ambient air standards.

All the receptors above the 24-hour threshold NO_x value of 368 micrograms per cubic meter were identified from the output table listing of 50-maximum 24-average concentration values. The resulting 50-maximum value table includes several header records identifying the concentration, date for the modeled concentration (ending hour of the averaging period), and the receptors (X and Y coordinates).

Based on the ISCST3 output file, there are only two 24-hour concentrations above 368 micrograms per cubic meter. To demonstrate compliance with the ambient air standard, OLM analysis was conducted for these two receptors.

Estimation of NO_2 Concentrations Resulting from NO_x Point Sources

- The first step is to use a screening technique (a standard Gaussian dispersion model [ISCST3]) to estimate the maximum NO_x concentrations.
- The second step involves estimating the fraction of this NO_x concentration occurring as NO_2.

Although NO_2 may be emitted directly to the atmosphere, most of it is formed as a result of reactions between NO and various other gases. The reaction with ozone is an effective means of converting NO to NO_2. In heavily polluted areas, reaction between NO and organic radicals provides an additional source of NO_2. A third source of NO_2 is the thermal conversion process:

$$2NO + O_2 = 2NO_2.$$

Ozone Limiting Method. The Ozone Limiting Method (OLM) involves an initial comparison of the estimated maximum NO_x concentration, (NO_x)max and the ambient O_3 concentration to determine which is the limiting factor to NO_2 formation.

If the O_3 concentration is greater than (NO_x)max, total conversion is assumed. If (NO_x)max is greater than the O_3 concentration, the formation of NO_2 is limited by the ambient O_3 concentration.

<u>The following expressions detail the procedure</u>:

1. A standard dispersion model ISCST3 is used to calculate (NO_x)max.

2. (NO_x)max is separated into two components:

   - Thermal conversion portion. For combustion sources, this is estimated to be equal to $0.10(NO_x)$max.
   - The remaining NO subject to conversion by O_3 equal to $0.90\ (NO_x)$max.

3. If (O_3)ambient is greater than $0.90(NO_x)$max, then assume that all of the NO is converted to NO_2, i.e., (NO_2)max = (NO_x)max.

   If $0.90(NO_x)$max is greater than (O_3)ambient, then set (NO_2)max = (O_3)ambient + $0.10(NO_x)$max.

4. (NO_2)max computed for the source is added to the NO_2 background.

The OLM program used for this analysis was BEE-LINE Software Inc., Version 2.5 (1995). In the OLM analysis, the default value for the NO_2 factor, micrograms per cubic meter to parts per million, is 1882.8091. This is one of the required input values by the OLM model. The corrected value (according to Bureau's Dispersion Modeling Guidelines) at an elevation of 7,000 feet is 1,473.4 micrograms per cubic meter, which was used in this OLM analysis.

Based on this OLM run, none of the receptors was found to exceed the NO_2 ambient air 24-hour standard of 147 micrograms per cubic meter. The maximum ozone corrected NO_2 value was only 90 micrograms per cubic meter. Therefore, maximum modeled NO_2 concentrations are below the applicable standards.

As shown in the following table, estimated criteria pollutant concentrations from combustion sources at LANL were within (i.e., less than) all national or State of New Mexico AAQS.

Results of Criteria Pollutants Analysis—Expanded Operations Alternative

POLLUTANT	TIME PERIOD	MAXIMUM ESTIMATED LANL IMPACTS (µg/m^3)	ASSUMED BACKGROUND CONCENTRATIONS[a] (µg/m^3)	TOTAL POLLUTANT CONCENTRATIONS (µg/m^3)	CONTROLLING AMBIENT AIR QUALITY STANDARDS (µg/m^3)[b]
Carbon Monoxide	1 hour	2,712	2,350	5,062	11,750
	8 hours	1,436	1,560	2,996	7,800
Nitrogen Dioxide[c]	24 hours	90[c]	29	119	147
	Annual	9	15	24	74
Sulfur Dioxide	3 hours	254	205	459	1,025
	24 hours	130	41	171	205
	Annual	18	8	26	41
Total Suspended Particulates	24 hours	18	30	48	150
	Annual	2	12	14	60
PM_{10}	24 hours	9	30	39	150
	Annual	1	10	11	50
Lead	3 months (calendar quarter)	0.7×10^{-4}	0.30	0.30	1.5

[a] No data exists for background values. It was conservatively assumed that background concentrations were 20 percent of the corresponding standard. Because there are almost no other combustion sources in and around LANL, the background concentrations would be much less than the 20 percent assumed concentrations.

[b] New Mexico Ambient Air Quality standards for some of the pollutants are stated in parts per million (ppm). These values were converted to micrograms per cubic meter (µg/m^3), with appropriate corrections for temperature and pressure (elevation) following New Mexico Dispersion Modeling Guidelines (revised January 1996).

[c] New Mexico Air Quality Bureau accepts OLM to more accurately determine NO_2 concentrations. The 24-hour maximum modeled concentration for NO_x was 520 µg/m^3. This concentration, when modeled using OLM, is only 90 µg/m^3 for NO_2.

Note: Ozone Analysis: Hourly ozone monitoring data from the BNM monitoring station for 1992 to 1994 were analyzed. The 1-hour of the fourth-highest values for the years 1992, 1993, and 1994 are 0.070 ppm, 0.066 ppm, and 0.072 ppm, respectively. The 3-year average of the annual fourth-highest maximum 1-hour concentration is 0.069 ppm. This value is about 58 percent of the 1-hour standard of 0.120 ppm. Therefore, DOE believes that when 8-hour data are analyzed in the future, these would show lower values than the new 8-hour standard of 0.08 ppm.

Notes:
[1] TA–16 emission factors in tons/MMSCF for the low NO_x boilers were provided by boiler manufacturer (Sellers Engineering Co., Danville, Kentucky, July 1995).
[2] TA–16 prototypical boiler unit capacity is a total capacity of all TA–16 boilers, except replacement (package) boilers, which were modeled separately.
[3] Miscellaneous prototypical boiler output capacity is a total capacity of boilers at each TA. Unit capacity is obtained from output capacity using the boiler efficiency of 72%.
[4] All miscellaneous boilers and replacement boilers at TA–16 are natural gas fired (Title V application) (LANL 1995b).
[5] Water pump engine has capacity of 700 hp, emission factors for water pump are in g/hp-hr.
[6] According to AP-42 (EPA 1995) particulate matter from the natural gas combustion is less than 1 μm in size, so ER(PM_{10}) = ER(TSP).
[7] TSP EF from the fuel oil #2 is the same as in Title V application (LANL 1995b); PM_{10} EF is obtained from Table 1.3–5 for size-specific EF from industrial boilers (EPA 1995).
[8] Waste oil and solid waste are burned. 8-hour CO and 24-hour SO_2 concentrations were conservatively estimated with 1-hour (CO) and 3-hours (SO_2) average emission rates.
[9] The second stacks at steam plants at TA–3 and TA–21 are used for standby or emergency operations only and were not taken into account (LANL 1995b).
EF = Emission Factor, EG = Emergency Generators, ER = Emission Rate, HP = horse power, SCF = standard cubic foot, TSP = Total Suspended Particulates

Notes:
[a] All emergency generators design capacities at a particular TA are total capacity of all of the same fuel fired generators.
[b] Emission factors for the diesel fired generators differ depending on the size of the generator; industrial generators are those with capacity up to 457 kW (600 hp) generators above this limit are considered large stationary diesel engines (in the table they are marked with an asterisk). If industrial generators are in the same TA as smaller generators, ER for industrial generators are presented separately.
[c] Particulate emissions for gasoline fueled generators and small industrial generators in size distribution were not available. It was assumed that ER(TSP) = 2 x ER(PM_{10}).
[d] Insignificant sources like small movable generators or TA–57 emergency generators were not included in this analysis. Emissions from Rover Street PA40 generator and 6th Street Cummins generator were added to the TA–3 diesel generator emissions.

TABLE C.—*Annual Average Emission Rates Used for the Combustion Source Analysis*

Notes:
[a] According to AP-42 (EPA 1995), particulate matter from the natural gas combustion is less than 1µm in size, so ER(PM_{10}) = ER(TSP).
[b] TSP EF from the fuel oil #2 is the same as in Title V application; PM_{10} EF is obtained from Table 1.3–5 for size-specific EF from industrial boilers (EPA 1995).
[c] Waste oil and solid waste was burned. 8-hour CO and 24-hour SO_2 concentrations were conservatively estimated using 1-hour (CO) and 3-hours (SO_2) emission rates.
[d] In the first column, a miscellaneous prototypical boiler is a boiler that sums up emissions from all boilers at this TA.

ATTACHMENT 2
TOXIC CHEMICALS CONSIDERED FOR THE ANALYSIS

Toxic Chemicals Considered for the Analysis

NO.	TOXIC AIR POLLUTANTS
	NONCARCINOGENIC POLLUTANTS
1	1,1-Dichloroethane
2	1,1,2-Trichloro-1,2,2-Trifluoroethane
3	1,1-Dichloro-Nitroethane
4	1,4-Dioxane
5	1,1,1-Trichloroethane
6	1,2,4-Trimethylbenzene
7	1,2-Dichloroethylene
8	1,3,5-Trimethylbenzene
9	1-Chloro-1-Nitropropane
10	1-Nitropropane
11	2,4,6-Trinitrotoluene (TNT)
12	2-Aminopyridine
13	2-Butoxyethanol
14	2-Butoxyethanol Acetate
15	2-Diethylaminoethanol
16	2-Ethoxyethanol (EGEE)
17	2-Ethoxyethyl Acetate (EGEEA)
18	2-Hydroxypropyl Acrilate
19	2-Methoxyethanol (EGME)
20	2-Methoxyethyl Acetate
21	2-Methyl-Cyclopent. Mang.Tricarbonyl
22	4-Methoxyphenol
23	a-Methyl Styrene
24	Acetic Acid
25	Acetic Anhydride
26	Acetone
27	Acetonitrile
28	Acetophenone
29	Acetylene
30	Acetylene Tetrabromide

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
31	Acrolein
32	Acrylic Acid
33	Adiponitrile
34	Allyl Alcohol
35	Allyl Glycidyl Ether (AGE)
36	Aluminum, Metal Dust, as Al
37	Aluminum Alkyls not otherwise classified
38	Aluminum Pyro Powders, as Al
39	Aluminum, Welding Fumes, as Al
40	Amitrole
41	Ammonia
42	Ammonium Chloride (Fume)
43	Aniline and Homologues
44	Anisidine (o-, p-isomers)
45	Antimony and Compounds, as Sb
46	Arsine
47	Asphalt (Petroleum) Fumes
48	Benzenethiol
49	Benzoyl Peroxide
50	Biphenyl
51	Bismuth Telluride
52	Boron Oxide
53	Boron Trifluoride
54	Bromine
55	Bromine Pentafluoride
56	Bromoform
57	Butyl Mercaptan
58	Carbon Black
59	Carbon Disulfide
60	Carbon Tetrabromide
61	Catechol
62	Cesium Hydroxide

Toxic Chemicals Considered for the Analysis-Continued

NO.	TOXIC AIR POLLUTANTS
63	Chlorinated Camphene
64	Chlorine
65	Chlorine Trifluoride
66	Chloroacetaldehyde
67	Chloroacetyl Chloride
68	Chlorobenzene
69	Chlorodifluoromethane
70	Chromium III comp., as Cr
71	Cobalt Carbonyl, as Co
72	Cobalt Hydrocarbonyl, as Co
73	Cobalt, el. & inorg. comp., as Co
74	Copper, Dusts & Mists, as Cu
75	Copper, Fume, as Cu
76	Cresol (all isomers)
77	Crotonaldehyde
78	Cumene
79	Cyanamide
80	Cyanogen
81	Cyanogen Chloride
82	Cyclohexane
83	Cyclohexanol
84	Cyclohexanone
85	Cyclohexene
86	Cyclohexylamine
87	Cyclopentadiene
88	Cyclopentane
89	Decaborane
90	Di-sec, Octyl Phthalate
91	Diacetone Alcohol
92	Diazinon
93	Diazomethane
94	Dibutyl Phosphate

Toxic Chemicals Considered for the Analysis-Continued

NO.	TOXIC AIR POLLUTANTS
95	Dibutyl Phthalate
96	Dichlorodifluoromethane
97	Dichlorofluoromethane
98	Dichlorovos
99	Dicyclopentadiene
100	Dicyclopentadienyl Iron
101	Diethyl Ketone
102	Diethyl Phthalate
103	Diethylamine
104	Diethylene Triamine
105	Diisoproprylamine
106	Dimethoxymethane
107	Dimethyl Amine
108	Dimethyl Phthalate
109	Dimethyl Sulfate
110	Dinitro-o-Cresol
111	Dinitrobenzene (all isomers)
112	Dinitrotoluene
113	Diphenylamine
114	Dipropyl Ketone
115	Diprop. Glycol Methyl Ether
116	Divinyl Benzene
117	Endrin
118	Enflurane
119	Ethanol
120	Ethanolamine
121	Ethion
122	Ethyl Acetate
123	Ethyl Benzene
124	Ethyl Bromide
125	Ethyl Chloride
126	Ethyl Ether

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
127	Ethyl Formate
128	Ethyl Mercaptan
129	Ethylamine
130	Ethylene Chlorohydrin
131	Ethylene Diamine
132	Fibrous Glass Dust
133	Fluorides, as F
134	Fluorine
135	Formamide
136	Formic Acid
137	Furfural
138	Furfuryl Alcohol
139	Gasoline
140	Germanium Tetrahydride
141	Glutaraldehyde
142	Hafnium
143	Hexafluoroacetone
144	Hexamethylene Diisocyanate
145	Hexane (other isomers)*
146	Hexylene Glycol
147	Hydrogen Bromide
148	Hydrogen Chloride
149	Hydrogen Cyanide
150	Hydrogen Fluoride, as F
151	Hydrogen Peroxide
152	Hydrogen Sulfide
153	Hydroquinone
154	Indene
155	Indium & compounds, as In
156	Iodine
157	Iodoform
158	Iron Oxide Fume, as Fe

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
159	Iron Pentacarbonyl, as Fe
160	Iso-Amyl Acetate
161	Iso-Amyl Alcohol
162	Isobutane
163	Isobutyl Acetate
164	Isobutyl Alcohol
165	Isobutyronitrile
166	Isooctyl Alcohol
167	Isophorone
168	Isophorone Diisocyanate
169	Isopropoxyethanol
170	Isopropyl Acetate
171	Isopropyl Alcohol
172	Isopropyl Ether
173	Isopropylamine
174	Kerosene
175	Lead, el. & inorg. compounds, as Pb
176	Lithium Hydride
177	m-Cresol
178	m-Phenylenediamine
179	m-Toluidine
180	Magnesium Oxide Fume
181	Maleic Anhydride
182	Malononitrile
183	Manganese Comp., as Mn
184	Manganese as Mn Fume
185	Mercury (in. forms, incl. m.Hg)
186	Mercury Alkyl Compounds
187	Mercury Aryl Compounds
188	Methacrylic Acid
189	Methoxychlor
190	Methyl 2-Cyanoacrylate

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
191	Methyl Acetate
192	Methyl Acetylene
193	Methyl Acrylate
194	Methyl Alcohol
195	Methyl Cyclohexane
196	Methyl Ethyl Ketone (MEK)
197	Methyl Formate
198	Methyl Hydrazine
199	Methyl Iodide
200	Methyl Isobutyl Carbinol
201	Methyl Isobutyl Ketone
202	Methyl Isocyanate
203	Methyl Mercaptan
204	Methyl Methacrylate
205	Methyl n-Amyl Ketone
206	Methyl n-Butyl Ketone
207	Methyl Propyl Ketone
208	Methyl Silicate
209	Methylacrylonitrile
210	Methylamine
211	Methylene Bisphenyl Isocyanate
212	Molybdenum as Mo Insol. Comp.
213	Molybdenum as Mo Sol. Comp.
214	Morpholine
215	n,n-Dimethyl Acetamide
216	n,n-Dimethylaniline
217	n,n-Dimethylformamide
218	n-Amyl Acetate
219	n-Butyl Acetate
220	n-Butyl Acrylate
221	n-Butyl Alcohol
222	n-Butyl Glycidyl Ether (BGE)

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
223	n-Butylamine
224	n-Heptane
225	n-Hexane
226	n-Methylaniline
227	n-Propyl Acetate
228	Naphtalene
229	Nickel Carbonyl, as Ni
230	Nickel Sol. & In. Comp., as Ni
231	Nicotine
232	Nitric Acid
233	Nitric Oxide
234	Nitrobenzene
235	Nitroethane
236	Nitromethane
237	Nitrotoluene
238	Nitrous Oxide
239	Nonane
240	o-Chlorostyrene
241	o-Chlorotoluene
242	o-Dichlorobenzene
243	o-Methylcyclohexanone
244	o-Phenylenediamine
245	o-Toluidine
246	Octane
247	Oil Mist, Mineral
248	Osmium Tetroxide, as Os
249	Oxalic Acid
250	p-Nitroaniline
251	p-Nitrochlorobenzene
252	p-Phenylenediamine
253	p-Toluidine
254	Paraffin Wax Fume

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
255	Paraquat Dichloride
256	Paraquat Respirable Sizes
257	Particulate Matter, Resp. Dust
258	Pentachlorophenol
259	Pentaerythritol
260	Pentane (all isomers)
261	Perchloromethyl Mercaptan
262	Phenol
263	Phenothiazine
264	Phenylhydrazine
265	Phenylphosphine
266	Phosgene
267	Phosphoric Acid
268	Phosphorus
269	Phosphorus Oxychloride
270	Phosphorus Pentachloride
271	Phosphorus Trichloride
272	Picric Acid
273	Platinum Metal
274	Potassium Hydroxide
275	Propane
276	Propargyl Alcohol
277	Propionic Acid
278	Propionitrile
239	Propyl Alcohol
280	Propylene Glycol Monomethyl Ether
281	Pyridine
282	Rhodium Metal
283	sec-Butyl Acetate
284	sec-Butyl Alcohol
285	Selenium Compounds, as Se
286	Silica, Cristobalite

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
287	Silica, Quartz
288	Tridymite, Respirable Dust
289	Silica, Fused (respirable)
290	Silicon Tetrahydride
291	Silver (met. dust & sol. comp., as Ag)
292	Stoddard Solvent
293	Sulfur Hexafluoride
294	Sulfuric Acid
295	Sulfuryl Fluoride
296	Tantalum Metal
297	Tellurium & Compounds, as Te
298	Terphenyls
299	tert-Butyl Alcohol
300	Tetraethyl Lead
301	Tetrahydrofuran
302	Tetranitromethane
303	Tetrasodium Pyrophosphate
304	Thioglycolic Acid
305	Thionyl Chloride
306	Tin, metal
307	Tin Organic Compounds, as Sn
308	Tin Oxide & Inorg. Comp., as Sn
309	Toluene
310	Toluene-2,4-diisocyanate (TDI)
311	Tributyl Phosphate
312	Trichloroacetic Acid
313	Triethylamine
314	Trimethyl Benzene
315	Trimethyl Phosphite
316	Trimethylamine
317	Triphenylamine
318	Triphenylphosphate

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
319	Tungsten as W insoluble Compounds
320	Turpentine
321	Uranium (nat.) Sol. & Unsol. Comp. as U
322	Vanadium, Respirable Dust & Fume
323	Vinyl Acetate
324	Vinyl Toluene
325	Vinylidene Fluoride
326	VM & P Naphtha
327	Welding Fumes not otherwise listed
328	Wood Dust (certain hard woods)
329	Xylene (o-, m-, p-Isomers)
330	Yttrium
331	Zinc Chloride Fume
332	Zinc Oxide Fume
333	Zinc Chromate, as Cr
334	Zirconium Compounds, as Zr
CARCINOGENIC POLLUTANTS	
335	Acetaldehyde
336	Acrylamide
337	Acrylonitrile
338	Allyl Chloride
339	Aldrin
340	Arsenic, el. & inorg., exc. Arsine, as As
341	Asbestos
342	Benzene
343	Benzidine
344	Benzo(a)pyrene
345	Benzyl Chloride
346	Beryllium
347	Bis(Chloromethyl)Ether (BCME)
348	1,3-Butadiene

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
349	Cadmium, el. & compounds, as Cd
350	Carbon Tetrachloride
351	Chloroform
352	Chlordane
353	Chromium VI
354	Diethanolamine
355	3,3-Dichlorobenzidine
356	Epichlorohydrin
357	Ethyl Acrylate
358	Ethylene Dibromide
359	Ethylene Dichloride
360	Ethylene Oxide
361	Formaldehyde
362	Hexachlorobenzene
363	Hexachlorobutadiene
364	Hexachloroethane
365	Hydrazine
366	Lindane
367	Methyl Chloride
368	Methylene Chloride
369	Nickel, metal (dust)
370	Polychlorinated Biphenyl (PCB)
371	Propylene Dichloride
372	Propylene Oxide
373	Styrene
374	Tetrachlorethylene
375	Trichloroethylene
376	Vinyl Chloride
377	1,1-Dichloethylene
378	1,1,2,2-Tetrachloroethane
379	1,1,1,2-Tetrachloroethane

***Toxic Chemicals Considered for the Analysis*-Continued**

NO.	TOXIC AIR POLLUTANTS
380	1,1,2-Trichloroethane
381	1,2-Dibromo-3-Chloropropane
382	2-Nitropropane

DISPERSION MODELING METHODOLOGY USED TO DEVELOP SCREENING LEVEL EMISSION VALUES

Dispersion Modeling Analysis

The EPA's Industrial Source Complex Air Quality Dispersion Model (ISC–3) was used for the dispersion analyses conducted for this study. The ISC–3 model, which applies a steady-state Gaussian plume equation for a continuous source, is a validated model that is often used to estimate air quality impacts from existing and proposed sources of air pollutants. The ISC–3's short-term algorithm was used to estimate 8-hour and annual concentrations at each of the receptor locations. Flat terrain was assumed. An emission rate of 1 gram per second was used to establish the relationship between emission rate and concentration at the maximum receptor location for each TA.

The regulatory default options that were used include:

- Rural dispersion algorithm
- Final plume rise
- Stack-tip downwash
- Building downwash
- Buoyancy-induced dispersion
- Default wind speed and vertical temperature profiles
- Terrain receptors, equal to and below the height of the lowest stack

The land use within or near Los Alamos (using the EPA-recommended Auer's technique [Auer 1978]) was considered to be rural. As such, the Pasquill-Gifford rural dispersion coefficients were used for all dispersion analyses.

Five years of Los Alamos meteorological on-site observations for years 1991 through 1995 were used in dispersion analysis for nonradiological air emissions. These 5 years of data were obtained by using the EPA PC RAMMET program, with surface observations and morning and afternoon mixing heights data as inputs. The surface observations were collected at the TA–6 meteorological tower at LANL. Mixing heights were estimated based on the Albuquerque upper air observations and Santa Fe surface data.

Because the TA stacks and nearby buildings may be subject to building downwash (i.e., stack heights may be less than good-engineering practice [GEP] stack heights), the controlling prototypical building dimensions were entered as input into the dispersion analysis. Trinity Consultants' Breeze Air™ (TCI 1996) BPIP (Building Profile Input Program [EPA 1993a]) computer software were used to determine direction-specific building dimensions (height, projected width, and GEP stack height).

Because there are no other significant sources of toxic air pollutants near LANL facilities, background air toxin levels were assumed to be zero.

The ISC–3-estimated maximum 8-hour and annual pollutant concentrations associated with LANL TAs, for a test case of 1 gram per second, using 1991 through 1995 meteorological data, are provided in Table A of this attachment.

Notes:
[a] 8-hour pollutant concentrations were estimated at the fence line receptors located around each TA.
[b] Annual pollutant concentrations were estimated at the sensitive receptors.
[c] Bold entries indicate that the highest concentration occurs for this year of the meteorological event.

TABLE 2 (PART A).—*Annual SLEVs of the Carcinogenic Pollutants from TA–3 Facilities*-Continued

NO.	CARCINOGENIC POLLUTANTS	CAS NUMBER	CAR. CLASS	UNIT RISK FACTOR (URF)	MAXIMUM CANCER RISK (C_{an} X URF)	ANNUAL SLEVS		RAPS 1990 DATA: ANNUAL EMISSION RATE FROM RAPS (Q^{aR})	RAPS 1990 DATA: RATIO SLEVS/ Q^{aR} (R^1)	NEW EMISSION RATE DATA: PURCHASED AMOUNT OF CHEMICALS FROM ACIS	NEW EMISSION RATE DATA: ESTIMATED ANNUAL EMISSION RATES (Q^{aA})	NEW EMISSION RATE DATA: RATIO SLEVS/Q^{aA} (R^2)	THE SMALLER (R^1) OR (R^2) RATIO
				(µg/m^3)$^{-1}$		g/sec	lb/yr	lb/yr		lb/year	lb/hr		
1	2	3	4	5	6	7	8	9	10	11	12	13	14
51	2-Nitropropane	79-46-9	B2	2.70E-03	6.66E-03	1.50E-06	2.38E-02						

Note: The highest ISC–3 estimated annual concentration at sensitive receptors set was found to be 2.465 µg/m3 when emission rate is 1 g/sec.
Note: ACIS and RAPS databases (LANL 1995a and LANL 1990) indicated that 51 carcinogens had been used in the past. Site information now shows 35 carcinogens in use (Attachment 6, Table C).

ATTACHMENT 6
ADDITIVE IMPACT ANALYSIS ASSOCIATED WITH THE COMBINED RELEASES OF CARCINOGENIC POLLUTANTS FROM ALL TECHNICAL AREAS

Technical Area(s): TA–00, TA–2, TA–3, TA–5, TA–8, TA–9, TA–11, TA–15, TA–16, TA–18, TA–21, TA–22, TA–33, TA–35, TA–36, TA–39, TA–40, TA–41, TA–43, TA–46, TA–48, TA–50, TA–51, TA–53, TA–54, TA–55, TA–59, TA–60, TA–61, and TA–64

Emission Sources

Releases of Noncarcinogenic and Carcinogenic Air Pollutants From All LANL TAs

Title III of the *Clean Air Act* (CAA) Amendments of 1990 sets a framework for regulating sources of toxic air pollutants. According to the provisions of the CAA, "after the implementation of the maximum achievable control technology, it is necessary to assess the residual risks due to toxic air emissions to the population near each source of emissions."

This assessment includes the determination of noncancer health effects of noncarcinogenic air pollutants based on the estimation of long-term and short-term ambient concentrations of these pollutants, and the determination of lifetime cancer risk exposure of carcinogenic air pollutants based on the estimation of long-term ambient concentrations of these pollutants. The determination involves performing analytical (modeling) simulations of the air pollutants dispersion for all emission sources of concern. Such simulations are then coupled with health effects information and compared to available population data to quantify human exposure, noncancer health risk, cancer risk, and ecological risks.

For carcinogenic air pollutants, the level of concern is the risk of an individual contracting cancer by being exposed to ambient concentrations of that pollutant over the course of a lifetime, or lifetime cancer risk. The criteria specified in the CAA is 1.0×10^{-6} (1 in 1,000,000) lifetime cancer risk for the individual exposed to the highest predicted concentration of a pollutant. Lifetime cancer risk is estimated by multiplying the predicted annual ambient concentration (in micrograms per cubic meter) of a specific pollutant by the unit risk factor for that pollutant, where the unit risk factor is equal to the upper bound lifetime cancer risk associated with inhaling a unit concentration (1 microgram per cubic meter) of that pollutant.

EPA has developed unit risk factors for a number of possible, probable, or known human carcinogens, which are available from its Integrated Risk Information System (IRIS) database.

According to EPA 1992f, "cancer risks resulting from exposure to mixtures of multiple carcinogenic pollutants are to be assessed by summing the incremental cancer risks due to each individual pollutant, regardless of the type of cancer that may be associated with any particular carcinogen. Thus, this approach assumes that all cancer risks are additive and all worst-case impacts occur at the same location. While this assumption may not be very realistic, it does help to insure that results are conservative, and, therefore protective to the public."

Pollutant(s) Considered

Noncarcinogenic Pollutants

An analysis of potential short-term impacts at a TA's fence line receptors showed that the 8-hour impacts from the releases of that TA were significantly greater (i.e., more then two orders of magnitude) than the impacts from the releases of a nearby TA. This is because the TAs are relatively far apart in comparison to the distances between the emission sources of a TA and its fence line receptors. Therefore, it is unlikely that the additive short-term impacts of noncarcinogenic pollutants at the fence line receptors of a TA would be significantly different from the maximum concentrations previously estimated for that TA.

An analysis of annual potential impacts at sensitive receptors showed that these impacts were significantly less (i.e., less then two orders of magnitude) relative to the appropriate Guideline Values (GVs) than the corresponding short-term impacts at the fence line receptors. Therefore, it is unlikely that the additive annual impacts of the noncarcinogenic pollutants at the sensitive receptors would be significant.

Carcinogenic Pollutants

All carcinogenic air pollutants that are currently being used at LANL or are anticipated to be used under the future alternatives were included in the additive impact analysis.

TA–2, TA–5, TA–11, TA–36, TA–40, TA–41, and TA–64 do not currently use carcinogenic pollutants and do not anticipate using them under the future alternatives. As such, these TAs were not included in the additive impact evaluation.

Emission Rates of Pollutants Considered

Annual emission rates of the carcinogenic pollutants used were those developed for both key and non-key facilities for each pollutant that had an SLEV/Q ratio less than one, based on process knowledge and chemical usage for the Expanded Operations Alternative. For those carcinogenic pollutants released from key or non-key facilities, within both key and non-key TAs, for which such emission data were not specifically developed for this analysis, emission rates were estimated based on data either from the RAPS Report or ACIS database, or were assumed to be at SLEV levels.

Beryllium emissions from all LANL sources (i.e., TA–3 CMR Building 29, TA–3 Machine Shops Complex, TA–35 Building 213, and TA–55 Building 15 Chemical Laboratory) were modeled using LANL's permitted emission rates.

Estimated emission rates of each of the carcinogenic pollutants considered in the additive impacts analysis for releases of all carcinogenic pollutants from all TAs are presented in Table A.

Dispersion Modeling Analysis

The additive impact analysis was conducted with the EPA's ISC–3 Model using 5 years of on-site meteorological data. All buildings near emission sources within the zone of influence at each TA were included in the downwash effects evaluation.

The incremental cancer risk from the release of a pollutant was estimated by multiplying the maximum ISC–3-estimated annual average concentration of that pollutant by its unit risk factor.

Major Assumptions Used in the Dispersion Analysis

- Emissions would be released simultaneously from LANL operations over 8,760 hours a year.
- Incremental cancer risks are additive.
- There is no reduction of the ambient concentrations by entry into buildings and deposition within them.

Results

Releases of Each Carcinogenic Pollutant from All TAs

The potential additive impact of the emissions of each of the carcinogenic pollutants from all of the TAs was estimated by assuming that each pollutant was emitted from all of the TAs at the SLEV levels. The maximum receptor for the release from each TA was added to the maximum receptor from each of the other TAs. This analysis was conducted for one of the pollutants, and the results were applied to each of the other pollutants. This approach is legitimate because the relationship between SLEVs and GVs are identical for all of the pollutants for each TA due to the fact that they are based on the same dispersion-related X/Q (concentration related to the emissions) ratio.

Results of the analysis are presented in Table B. For illustrational purposes, the cancer risk associated with the releases of three pollutants (arsenic, benzene, and formaldehyde) at their SLEV release rates are shown in Table B.

As shown, the combined cancer risk associated with releases of each of these pollutants from all TAs is 1.23×10^{-7}, which is below the GV of 1.0×10^{-6}.

Releases of All Carcinogenic Pollutants from All TAs

A total of 35 carcinogenic pollutants were considered in the additive impacts analysis of emissions of all carcinogenic pollutants from all of the TAs. These are the carcinogenic pollutants that are currently being used at LANL or are anticipated to be used under the site's future alternatives. The annual average concentrations of each pollutant were estimated assuming that all pollutants were emitted simultaneously from all of the TAs.

The maximum concentration of each pollutant from the simultaneous release from all TAs was determined by modeling the emission rates from Table A and recording the highest concentration from a listing of 180 receptors. The combined cancer risk was then estimated by summing up the cancer risk of each individual pollutant at these (maximum) concentrations, even though the receptors may have been different. This value was then compared with an allowable incremental cancer risk of 1.0×10^{-6}. Results of this analysis are presented in Table C. As shown, the potential combined incremental cancer risk associated with releases of all carcinogenic pollutants from all TAs is above the GV of 1.0×10^{-6}.

Because the predicted combined additive impact of all carcinogenic pollutants released from all TAs is above the specified GV of 1.0×10^{-6}, a more detailed analysis that considered the impact at each receptor locations was conducted. This more refined analysis estimated the combined cancer risk at each of the 180 sensitive receptor locations with a focus on the pollutants with the greatest contribution to the combined cancer risk from the previous step.

For each of these critical pollutants (chloroform, formaldehyde, methylene chloride, and trichloethylene), the maximum cancer risk was estimated at each of the 180 receptor locations using the highest values of the annual concentrations estimated using 5 years of meteorological data for that receptor. Cancer risk values at receptors #28 and #175 through #180 (the highest values) were computed for all the other chemicals, also using the highest value of the annual concentration estimated using 5 years of meteorological data for those receptors. For receptors other than those just mentioned, default values of the maximum concentration of any of the receptors were recorded in Table D for each of the chemicals other than the four critical pollutants.

As shown in Table D, the combined incremental cancer risk associated with releases of all carcinogenic pollutants from all TAs at the receptor locations where these impacts actually occur are above the GV of 1.0×10^{-6} at the two locations within the LANL Medical Center, 1.17×10^{-6} at Receptor #175 (air intake duct at a height of 3.7 feet [12.2 meters]) and 1.07×10^{-6} at Receptor #180 (an operable window at a height of 0.46 feet [1.5 meters]).

The major contributors to the estimated combined cancer risk values are pollutants primarily released from TA–43, the Health Research Laboratory (HRL). The critical pollutants are chloroform, formaldehyde, and trichloethylene from the HRL and methylene chloride from multiple sources (TA–3, TA–9, TA–16, TA–35, TA–46, and TA–48). The estimated maximum cancer risk for each of these individual pollutants is 8.74×10^{-7}, 5.17×10^{-8}, 6.73×10^{-8}, and 6.84×10^{-8}, respectively. Of these, the relative contribution of chloroform emissions alone to the combined cancer risk value is more than 87 percent.

The impacts of TA–43 emissions are due to a combination of relatively high emission rates, close proximity between receptors and sources, and the elevation of the receptors. Receptors at or near the Medical Center, where these impacts are estimated, are #28 and #175 through 180 in attachment 3, Sensitive Receptors. Receptor #28 is a ground level receptor. Receptors #175 through 180 are elevated (i.e., air intakes at a height of up to 3.7 feet [12 meters] and operable windows at a height of 0.46 feet [1.5 meters] above the ground) and are at the distance of less than 30.5 feet (100 meters) from the nearest stack on the roof of the HRL.

Because the estimated cancer risk at these two receptor locations is above the GV of 1.0×10^{-6}, these results are subject to a risk assessment analysis.

35	Vinyl Chloride																

Notes: TA–2, TA–5, TA–11, TA–36, TA–40, TA–41, and TA–64, which are not currently using any of the carcinogenic pollutants or are anticipated to use them under future alternatives, were not included in the analysis.

[a] Beryllium emissions from all sources (i.e., TA–3 CMR Building 29, TA–3 Shop Complex, TA–35 Building 213, and TA–55 Building 15 Chemical Lab.), were modeled using LANL's permitted emission rates.

[b] Annual emission rates of carcinogenic pollutants were estimated based on detailed evaluation of actual operating conditions. These revised emission rates were developed for both key and non-key buildings, within key and non-key TAs, for each pollutant that had an SLEV/Q ratio less than 1. For those pollutants released from key or non-key buildings, within both key and non-key TAs, for which such emission data were not developed, emission rates were estimated based on data either from the RAPS–90 (LANL 1990) Report or ACIS 1996 database (LANL 1995a), or were assumed to be at SLEV levels.

[c] It was assumed that emissions would be released simultaneously over 8,760 hours a year.

SUMMARY				
Estimated Annual Concentration[b] from Releases of Each Pollutant from All TAs, (C_{an}), μg/m^3		2.82E-05	1.49E-02	9.49E-03
Unit Risk Factors[c] (URF), (μg/m^3)$^{-1}$		4.35E-03	8.30E-06	1.30E-05
Maximum Incremental Cancer Risk[d] (C_{an} x URF)		1.23E-07	1.23E-07	1.23E-07
Guideline Value[e]		1.00E-06	1.00E-06	1.00E-06

Major Assumptions:

[a] Annual emission rates at the SLEV levels were used in the additive impacts analysis.

[b] Annual average concentration (C_{an}) is the highest concentration estimated by the ISC–3model at any of the sensitive receptor locations using 5 years of on-site meteorological data.

[c] Unit risk factors are from the EPA's Integrated Risk Information System (IRIS) database (EPA 1993b).

[d] Maximum cancer risk of each pollutant was estimated by multiplying the annual concentration of that pollutant by its unit risk factor (EPA 1992f and EPA 1993b). Total combined incremental cancer risk was estimated by summing the cancer risks due to each individual pollutant released from all TAs.

[e] The guideline value of 1.0E-06 (1.0 x 10^{-6}), established by Title III of the *Clean Air Act Amendments of 1990* (CAAA) as a level of concern, is associated with a life time exposure to carcinogenic pollutants (EPA 1992f).

Total Combined Cancer Risk of All Pollutants[e]				1.67E-06
Guideline Value[f]				1.00E-06

Notes:
Major Assumptions:
[a] The total of 35 carcinogenic pollutants that have the potential to be released from LANL operations were considered in the additive impact analysis. Emission rates of these pollutants are presented in Table A.
[b] ISC–3 estimated annual concentration is the highest concentration at any of the sensitive receptor locations using 5 years on-site of meteorological data.
[c] Unit risk factors are from the EPA's Integrated Risk Information System (IRIS) database (EPA 1993b).
[d] Maximum cancer risk was obtained by multiplying of the estimated annual concentration of a specific pollutant by its unit risk factor (EPA 1992f and EPA 1993b).
[e] The total potential combined cancer risks were estimated by summing the cancer risks due to each individual pollutant released from LANL operations, regardless of the location where maximum values are estimated.
[f] The guideline value of 1.0E-06 (1.0×10^{-6}), established by Title III of the *Clean Air Act Amendments of 1990* (CAAA) as a level of concern, is associated with a life time exposure to carcinogenic pollutants (EPA 1992f).

Receptor ID Numbers:
1. CHLF = Chloroform; 2. FORM = Formaldehyde; 3. TRCE = Trichloethylene; 4. MECH = Methylene Chloride; 5. Be = Beryllium; 6. MTCH = Methyl Chloride; 7. ETDC = Ethylene Dichloride; 8. CCL4 = Carbon Tetrachloride; 9. NI = Nickel; 10. BENZ = Benzene; 11. ACAL = Acetaldehyde; 12. ETAC = Ethyl Acrylate; 13. TECE = Tetrachloethylene; 14. PRDI = Propylene Dichloride; 15. STYR = Styrene; 16. CDDF = 2,3,7,8-Tetrachlorodibenzo(p)dioxin; 17. As = Arsenic; 18. Cd = Cadmium; 19. BNZP = Benzo(p)pyrene; 20. Cr VI = Hexavalent Chromium; 21. ACAM = Acrylamide; 22. 1.3-BUT = 1,3-Butadiene; 23. 2-NTP = 2-Nitropropane; 24. 1,1,1,2-TCE = 1,1,1,2-Tetrachloroethane; 25. 1,1,2,2-TCE = 1,1,2,2-Tetrachloroethane; 26. 1,1,2-Trichloroethane; 27. HECE = Hexachloroethane; 28. HECB = Hexachlobutadiene; 29. VINC = Vinyl Chloride; 30. DIEA = Diethanolamine; 31. EPCH = Epichlorhydrine; 32. ALCH = Allyl Chloride; 33. ETOX = Ethylene Oxide; 34. BNCH = Benzyl Chloride; 35. HDRZ = Hydrazine.

Notes:
Max. CR = Maximum cancer risk due to each pollutant.
Total Combined CR = total estimated cancer risk of all pollutants combined.

Dispersion Analysis:
- The additive impact analysis was conducted with the EPA's ISC–3 model using 5 years of on-site meteorological data.
- The total of 35 carcinogenic pollutants that have the potential to be released from LANL operations were considered in the analysis. Emission rates of these pollutants and the appropriate unit risk factors are presented in Tables A and C.
- Maximum cancer risk was obtained by multiplying of the estimated annual concentration of a specific pollutant by its unit risk factor (EPA 1992f and EPA 1993b).
- The total potential combined cancer risks were estimated by summing the cancer risks due to each individual pollutant at each of the 180 receptor locations.

Major Assumptions:
- Emissions would be released simultaneously from LANL operations over 8,760 hours a year.
- Incremental cancer risks are additive.

Other Assumptions Include:
- All chemicals are released to the atmosphere, rather than used in process or product or sent to waste disposal or recycling after use.
- There is no time spent indoors or inside automobiles; whereas, people actually spend more than 80% of their time indoors. Being inside would cut the concentration by half as a minimum.

ATTACHMENT 7
AIR QUALITY IMPACT ASSESSMENT OF THE TA–3 CHEMICAL AND METALLURGY RESEARCH FACILITY (CMR) METHYLENE CHLORIDE EMISSIONS

Technical Area: TA–3, CMR Facility

Emission Source(s)

An emission source of methylene chloride is located at the CMR Facility, Building 29 (Stack ID FE–20). Methylene chloride is used for analysis of soil samples. During the concentrating phase, the extracted methylene chloride is evaporated and emitted to the atmosphere.

Source Term Parameters

Stack parameters and their locations are provided in Table A.

Emission Rates of Pollutants Considered

The annual emission rate of methylene chloride was estimated to be 700 pounds a year under the Expanded Operations Alternative operating schedule (Table A). It was assumed that these emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

Air quality impacts analysis was conducted with the EPA's ISC–3 Model using 5 years of on-site meteorological data. All nearby buildings within the zone of plume influence were considered in the downwash analysis. The highest annual average concentration estimated by the ISC–3 Model at any of sensitive receptors was used to estimate the incremental cancer risk of the methylene chloride release using its unit risk factor.

Results

Results of the analysis are presented in Tables B and C. As shown in Table C, the maximum cancer risk associated with release of methylene chloride from Building 29 of the TA–3 CMR facility is below the Guideline Value of 1.0×10^{-8}.

ATTACHMENT 8
AIR QUALITY IMPACT ASSESSMENT OF THE TA–3 BERYLLIUM EMISSIONS

Technical Area: TA–3, Buildings 102 and SM141

Emission Source(s)

Beryllium process development and machining operations at TA–3 are conducted in support of ongoing beryllium research and are currently being refurbished. Beryllium machining operations conducted at TA–3–39 will be relocated to the new Sigma beryllium TA–3–141 in order to consolidate the majority of the beryllium processing conducted at LANL. The permitted beryllium operations conducted at TA–3–102, TA–35–213, and TA–55, and the registered beryllium sources at TA–3–29 and TA–66 will remain in place. The modified SM141 beryllium facility also will incorporate operations and equipment from other DOE complexes.

Emissions from the two stacks, one on the TA–3 Building 102, and the other on the Building SM141, were considered in the analysis.

Source Term Parameters

Stack parameters and their locations are shown in Table A.

Emission Rates of Pollutants Considered

Annual emission rates of beryllium were estimated based on the draft permit application for SM141 and the existing air quality permit for the TA–3–102 facility. Emissions from these facilities are released to the atmosphere through a high efficiency particulate air (HEPA) filtration system, with a removal efficiency of 99.95 percent. Controlled emission rates are estimated to be 0.11 pounds per year for SM141 facility, and 1.4×10^{-4} pounds per year for the TA–3–102 facility.

Estimated annual emission rates of beryllium that were used in the analysis are shown in Table A. It was assumed that emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA’s ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings, including Buildings 102 and SM141, within the zone of stack plume influence were considered in the downwash analysis. The highest annual concentration estimated by the ISC–3 Model (Table B) was used to compute the maximum combined cancer risk of beryllium releases using its unit risk factor.

Results

Results of the analysis are presented in Tables B and C. As shown in Table C, the combined cancer risk associated with releases of beryllium from Buildings 102 and SM141 of the TA–3 facility is 2.41×10^{-9}, which is below the Guideline Value of 1.0×10^{-8}.

ATTACHMENT 9
AIR QUALITY IMPACT ASSESSMENT OF THE TA–3 SHOPS COMPLEX NICKEL DUST EMISSIONS

Technical Area: TA–3, Shops Complex

Emission Source(s)

The Shops Complex contains machining and inspection equipment to support LANL. The missions supported include nuclear weapons technology, stockpile management, nuclear materials production, and general fabrication. Nickel is machined in Building 102 of the Shops Complex facility.

Source Term Parameters

Stack parameters and locations are provided in Table A.

Emission Rates of Pollutants Considered

The nickel dust generated from the machining process is exhausted through a series of in-line high efficiency particulate air (HEPA) filters before entering a common shops baghouse control system and exiting to the atmosphere. The HEPA filter has a rated control efficiency of 99.97 percent, and the baghouse has a measured control efficiency of 80 percent. The amount of nickel currently being machined is approximately 10 percent of what was machined in 1990. The estimated annual emission rate of the nickel dust used in the dispersion analysis is shown in Table A. It was assumed that annual emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted with EPA's ISC–3 Model using 5 years of on-site meteorological data. All nearby buildings within the zone of plume influence were considered in the downwash analysis. The highest annual average concentration estimated by the ISC–3 Model at any of sensitive receptors was used to estimate the incremental cancer risk of the nickel release using its unit risk factor.

Results

Results of the analysis are presented in Tables B and C. As shown in Table C, the maximum cancer risk associated with release of the nickel dust from Shops Complex Building 102 of the TA–3 facility is below the Guideline Value of 1.0×10^{-8}.

ATTACHMENT 10
AIR QUALITY IMPACT ASSESSMENT OF PAINT BOOTH EMISSIONS

Technical Areas: TA–3, Building 38; TA–3, Building 39; and TA–60, Building 17

Emission Source: Paint Booth Operations

Paint booth operations occur at TA–3–38, TA–3–39, and TA–60–17.

Pollutant(s) Considered

There are seven toxic, noncarcinogenic pollutants and one carcinogenic air pollutant that have the potential to be released into the atmosphere from the paint booth located at TA–3–38. The noncarcinogenic pollutants are 2-butoxyethanol, isobutyl acetate, isopropyl alcohol, toluene, trimethyl benzene, xylene, and particulate matter. The carcinogenic pollutant is benzene. These chemicals are constituents of oil-based paint and paint thinner. Of these, toluene, trimethyl benzene, xylene, and benzene are constituents of oil-based paint. Isopropyl alcohol, 2-butoxyethanol, isobutyl acetate, and toluene are constituents of the paint thinner.

Because the chemical composition of the paints and thinner at TA–3–39 and TA–60–17 were not provided, it was assumed that paints and thinner compositions to be used at paint booths at TA–3–39 and TA–60–17 are similar to those used at the TA–3–38 paint booth.

Emission Rates of Pollutants Considered

To estimate annual emissions from painting operations from the paint booths, the information giving the quantity of paints and thinner used annually at each TA and their density was obtained. This information is presented in Tables A through E for each TA in the footnotes. It was assumed that type and duration of painting operations conducted at TA–60–17 in 1994 (i.e., 528 hours per year of operations consisted of 240 hours per year of rack painting, plus 288 hours per year of maintenance painting) would apply to all painting activities conducted at the TA–3–38 and TA–3–39 paint booths. Hourly emission rates were estimated for 528 hours of operations per year using a correction factor of five to approximate maximum hourly emission rates. That is, the hourly emission rates were estimated by dividing annual emission rates by 528 hours and then multiplying this value by five.

Estimated hourly and annual emission rates of toxic (noncarcinogenic and carcinogenic) air pollutants from paint booths at TA–3–38, TA–3–39, and TA–60–17 are presented in Tables A through F.

Emissions were modeled with EPA's ISC–3 Model as point sources located on specified buildings (TA–3 Buildings 38 and 39, TA–60 Building 17). The source terms were estimated based on engineering judgment (stack height = 32.8 feet [10 meters], building height = 31.17 feet [9.5 meters], stack diameter = 1.15 feet [0.35 meters], exit velocity = 16.41 feet per second [5 meters per second], and exit temperature = 293°K).

Two paint booth impact analyses were conducted, one to estimate short-term (8-hour) impacts of noncarcinogenic and carcinogenic pollutants, and one to estimate long-term annual impacts of carcinogenic pollutants.

Major Assumptions Used in the Analysis

- All paints and thinners used at TA–3–39 and TA–60–17 have similar composition and constituents as those identified for paints and thinner at TA–3–38.
- The type and duration of painting operations conducted at TA–60–17 would apply to all painting activities conducted at TA–3–38 and TA–3–39 paint booths.
- Content of fine particles (less than 10 micrometers in size) is 50 percent of the total particulate matter content.
- Five percent of PM_{10} content would be released into the atmosphere through the emission control equipment.

Results

Analysis of short-term (8-hour) impacts of noncarcinogenic air pollutants that have the potential to be released into the atmosphere under baseline conditions and under future alternatives show no impacts on ambient air quality. The $SLEV/Q^h$ ratios for all pollutants considered are all greater than one (Tables A, C, and E). That is, the estimated pollutant levels are below the established Guideline Values (GVs).

Results of the annual impacts analysis of the carcinogenic pollutant presented in Tables B, D, and F show that benzene emitted from TA–3–38 and TA–60–17 failed the analysis with an $SLEV/Q^{an}$ ratio less than one. That is, the estimated benzene level is greater then the established GV. This pollutant was further evaluated in the additive impact analysis.

TABLE A.—*8-Hour SLEV/Q Ratios of the Toxic (Noncarcinogenic and Carcinogenic) Air Pollutants from TA–3–38 Paint Booth*[1]

Site Operations Data:

- The amount of oil-based paint used annually is 250 gal./year.
- The constituents of the paint are toluene (5% by weight), trimethyl benzene (5% by weight), xylene (30% by weight), and benzene (0.1% by weight).
- The highest density of the paint is 9.1 lb/gal.
- The amount of paint thinner used annually with a density of 6.9 lb/gal. is 56 gal.
- The constituents of the thinner are toluene (10% by weight), isopropyl alcohol (20% by weight), 2-Butoxyethanol (10% by weight), and isobutyl acetate (35% by weight).

Notes:

Major Assumptions:

[1] Type and duration of painting operations conducted at TA–60–17 in 1994 (528 hours of operation consisted of 240 hours/year of rack painting, plus 288 hours/year of maintenance painting) would apply to all painting activities conducted at TA–3–38 paint booth.

[2] Hourly emission rates were estimated based upon 528 hours/year of operation using a correction factor of five to approximate the maximum potential hourly emission rate.

[3] Particulate emissions of 10 micrometers in size (PM_{10}) were estimated based upon the solids content of a paint and amount of total particulates emitted from TA–3–38 paint booth (844 lb/year).

[4] Content of fine particles PM_{10} is 50% of the total particulate matter content.

[5] 5% of the PM_{10} content would be released into the atmosphere.

Guideline Value(s):

[6] OEL = occupational exposure limits established by the American Conference of Governmental Industrial Hygienists (ACGIH 1997).

[7] 1/100 of the OEL is 8-hour guideline value used in the analysis to estimate short-term impacts of the toxic air pollutants.

Dispersion Analysis Results:

[8] 5 years of meteorological data were used in the dispersion modeling analysis. The highest ISC–3 estimated 8-hour concentration at fence line receptors was found to be 264.1 $\mu g/m^3$ when emission rate is 1 g/sec.

NA = Not applicable

TABLE B.—*Annual SLEV/Q Ratios of the Carcinogenic Pollutants from TA–3–38 Paint Booth*

NO.	CARCINOGENIC POLLUTANT	CAS NUMBER	CAR CLASS	UNIT RISK FACTOR (URF)	MAXIMUM CANCER RISK (C_{an} x URF)[3]	ANNUAL SLEV[1]		ANNUAL EMISSION RATE (Q^a)[2]	RATIO SLEV/Q^a

[3] The benzene content of the paint is the same as for the paint booth at TA–3–38 (0.1% by weight).

Dispersion Analysis Results:

[4] 5 years of meteorological data were used in the dispersion modeling analysis. The highest ISC–3 estimated annual concentration at sensitive receptors was found to be 4.85 $\mu g/m^3$ when emission rate is 1 g/sec.

ATTACHMENT 11
AIR QUALITY IMPACT ASSESSMENT OF INCINERATOR EMISSIONS

Technical Area: TA–16

Emission Source(s): Incineration of HE-Contaminated Paper and Oil

Two incinerator impact analyses were conducted, one for burning high explosives (HE)-contaminated paper waste and one for burning HE-contaminated oil.

Incineration of HE-Contaminated Paper Waste

Maximum Firing Rate

The maximum HE-contaminated paper waste firing rate was estimated to be 2,204.6 pounds (1,000 kilograms) per year in order to reflect the maximum amount of paper waste currently burned under baseline conditions and the expected maximum amount that is anticipated to be burned under any of the future alternatives.

Source Term Parameters (from incinerator specifications)

- Incinerator stack height above ground level = 28.15 feet (8.58 meters)
- Stack inner diameter = 1.83 feet (0.559 meters)
- Stack exit velocity = 22.97 feet per second (7 meters per second) (assumed based on engineering judgment)
- Stack exit temperature = 800°F (427°C) (assumed based on engineering judgment)
- Stack location = south-east corner of Building 1409 of TA–16

Pollutant(s) Considered

Pollutants usually associated with the combustion of paper and wood waste are metals, acid gases, toxic organics such as CDD/CDF (i.e., groups of chlorinated homologs of dioxins and furans), and criteria pollutants (CO, NO_x, SO_2, and PM_{10}). For conservativeness, only toxic pollutants with the highest toxicity and carcinogenicity, such as arsenic, hexavalent chromium, cadmium, nickel, and CDD/CDF were selected for evaluation.

Emission Rates of Pollutants Considered

Emission factors for toxic and criteria pollutants considered were obtained from EPA's "Compilation of Air Pollutant Emissions Factors" (EPA 1995) (Table 2.1-9) for modular starved air combustors burning solid waste. Emission factors for criteria pollutants were used for estimating long-term emission rates because they are based only on long-term monitoring data.

Estimated annual emission rates of the toxic and criteria pollutants that are based on the most recent AP–42 emission factors are shown in Tables A and B, respectively.

Major Assumptions

- Incinerator would operate 250 hours a year (one burn per day, 5 days per week, and 50 weeks per year).
- 30 percent of the total chromium would be released in the form of hexavalent chromium.
- Emissions would be released over 8,760 hours of operation per year.
- The content of fine particulates (less than 10 micrometers in size) is 50 percent of the total particulate matter emitted.

Results

Toxic Air Pollutants. Because all of the toxic pollutants to be considered in the analysis are carcinogenic and annual impacts from these pollutants on ambient air are much more significant than the short-term (8-hour) impacts, only annual impacts were considered. As shown in Table A, only one of the pollutants considered (CDD/CDF) had an estimated pollutant level greater than the established Guideline Value (GV) (i.e., the SLEV/Q^a ratio is less than 1). This pollutant will therefore be further evaluated as a part of the additive impact analysis. None of the releases of other toxic pollutants would result in air quality impacts.

Criteria Air Pollutants. As shown in Table C, estimated annual concentrations of the criteria pollutants (C^{an}) are below the NAAQS. That is, the NAAQS/C^{an} ratios are always greater than 1. None of the releases of criteria pollutants would result in air quality impacts.

Incineration of HE-Contaminated Oil

Maximum Firing Rate

The maximum HE-contaminated oil firing rate is 1,200 gallons (4,542.48 liters) annually and 10 gallons (37.85 liters) hourly.

Source Term Parameters

The source term parameters are the same as were used in the analysis of HE-contaminated paper waste.

Pollutant(s) Considered

HE-contaminated oil generated by the High Explosives Processing Facility (HEPF) is not a "traditional waste oil," and many of the toxic air pollutants (such as metals) are not constituents of HE-contaminated oil. Therefore, metals were not considered in this analysis. The composition of VOCs were determined using EPA data (EPA 1995). Based on these data, it was assumed that, with the exception of metals, some specified organic compounds from VOCs, such as phenol, dichlorobenzene, naphthalene, and benzo(p)pyrene, may be formed as products of incomplete combustion. There also are acid gases, such as hydrogen chloride that are usually detected in flue gases from waste oil combustion. Based on these findings, toxic pollutants from waste oil burning were considered.

Emission Rates of Pollutants Considered

Emission factors for toxic and criteria air pollutants were obtained from Tables 1.11-1, -2, -3, and -5 of EPA 1995 for waste oil combustors. Estimated maximum hourly emission rates of the toxic noncarcinogenic and criteria air pollutants are presented in Table D. Estimated annual emission rates of the toxic carcinogenic pollutants and criteria pollutants are shown in Tables E and F, respectively.

Major Assumptions

- Incinerator would operate 250 hours a year (one burn per day, 5 days per week, and 50 weeks per year).
- Emissions would be released over 8,760 hours of operation per year.
- Percent of chlorine in oil is 0.1 percent by weight.
- Percent of ash in oil is 1 percent by weight.
- Sulfur content in oil is 1 percent by weight.

Results

Toxic Air Pollutants. Both short-term (8-hour) and long-term (annual) impacts of the toxic (carcinogenic and noncarcinogenic) air pollutants from waste oil incineration were considered. No pollutants failed the analysis (i.e., the estimated pollutant levels are below the established GV). As shown in Tables D and E, the SLEV/Q ratios are always greater than 1. None of the releases of toxic pollutants would result in air quality impacts.

Criteria Air Pollutants. As shown in Table G, estimated annual concentrations of the criteria pollutants (C^{an}) are below the NAAQS (i.e., the NAAQS/C^{an} ratios are always greater than 1). None of the releases of criteria pollutants would result in air quality impacts.

Source Term Parameters:
Source term parameters obtained from incinerator specification were as follows:
- Incinerator stack height above ground level is 8.58 m.
- Stack inner diameter is 0.559 m.
- Stack exit velocity is 7 m/sec (assumed).
- Stack exit temperature is 427°C.
- Stack location is southeast corner of Building 1409 of TA–16.

Maximum Firing Emission Rate:
Maximum amount of the material burned is 1,000 kilograms on an annual basis.
Notes:
Major Assumptions:
[1] Emission factors were obtained from EPA's AP–42 (EPA 1995), Tables 2.1–9 for modular starved air combustors burning solid waste.
[2] Annual average emission rates were estimated based on EPA's AP–42 emission factors and the maximum amount of material burned annually (EPA 1995).
[3] Annual SLEVs (lb/yr) were estimated assuming that incinerator would be operating 250 hours/year (one burn/day, 5 days/week, and 50 weeks/year).
[4] 30% of the total chromium was assumed to be released in the form of hexavalent chromium.
Disperion Analysis Results:
[5] 5 years of meteorological data (1991 to 1995) were used in the dispersion modeling analysis. The highest annual concentration of 0.36 $\mu g/m^3$ was found to occur during 1991.

TABLE B.—*Annual Emission Rates for the Criteria Pollutants from TA–16 Incinerator Burning HE-Contaminated Paper Waste*

NO.	CRITERIA AIR POLLUTANTS	AMOUNT OF WASTE BURNED ANNUALLY[a]	EPA'S AP–42 EMISSION FACTORS[b]		ANNUAL EMISSION RATE[c]

Source Term Parameters:

Source term parameters obtained from incinerator specification were as follows:

- Incinerator stack height above ground level is 8.58 m.
- Stack inner diameter is .559 m.
- Stack exit velocity is 7 m/sec (assumed).
- Stack exit temperature is 427°C (assumed).
- Stack location is southeast corner of Building 1409 of TA–16.

TABLE D.—*8-Hour SLEV/Q Ratios for the Toxic and Criteria Air Pollutants from TA–16 Incinerator Burning HE-Contaminated Oil*-Continued

Maximum Firing Emission Rate:
Maximum amount of oil burned (i.e.,10 gallons on an hourly basis) was obtained from EPA 1992f.
Notes:
Major Assumptions:
[a] Emission factors were obtained from EPA's AP–42, Tables 1.11–1, 2, 3, and 5 for waste oil combustors (EPA 1995). Toxic metal compounds such as arsenic, cadmium, chromium, etc., that are usually emitted from waste oil combustion, are not constituents of HE-contaminated oil. Therefore, toxic metals were not considered.
[b] Percent of chlorine in oil is 0.1% by weight,
[c] Percent of ash in oil is 1% by weight, and
[d] Sulfur content in oil is 1% by weight.
[e] Maximum hourly emission rates were estimated based on EPA's AP–42 emission factors and maximum amount of oil burned (EPA 1995).
Dispersion Analysis Results:
[f] 5 years of meteorological data (1991 to 1995) were used in the dispersion modeling analysis. The estimated maximum 8-hour concentration of 118.4 $\mu g/m^3$ was found to occur during 1992.

TABLE E.—*Annual SLEV/Q for the Toxic Carcinogenic Air Pollutants from TA–16 Incinerator Burning HE-Contaminated Oil*

NO	TOXIC CARCINOGENIC AIR POLLUTANTS	CAS NUMBER	CAR CLASS	UNIT RISK FACTOR (URF)	MAXIMUM CANCER RISK (C_{an} x URF)[e]	ANNUAL SLEVs[d]		EMISSION FACTORS[b]	AMOUNT OF OIL BURNED ON ANNUAL BASIS[a]	ANNUAL EMISSION RATE (Q_a)[c]	SLEVs/Q_a RATIO
				$(\mu g/m^3)^{-1}$		g/sec	lb/year 3	lb/gal.	gal./year	lb/year	
1	2	3	4	5	6	7	8	9	10	11	12
1	Benzo(a)pyrene	50-32-8	B2	1.70E-03	6.19E-04	1.62E-05	3.20E-02	4.00E-06	1.20E+03	4.80E-03	6.68E+00

Source Term Parameters:
Source term parameters obtained from incinerator specification were as follows:

- Incinerator stack height above ground level is 8.58 m.
- Stack inner diameter is 0.559 m.
- Stack exit velocity is 7 m/sec (assumed).
- Stack exit temperature is 427°C (assumed).
- Stack location is southeast corner of Building 1409 of TA–16.

Notes:
Maximum Firing Emission Rate:
[a] Maximum amount of oil burned (i.e., 1,200 gallons on an annual basis) was obtained from EPA 1992c.
Major Assumptions:
[b] Emission factors for benzo(p)pyrene were obtained from EPA's AP–42, Table 1.11–5 for waste oil combustors (EPA 1995).
[c] Annual average emission rate was estimated based on EPA's AP–42 (EPA 1995) emission factors and the maximum amount of oil burned annually (1,200 gallons), according to EPA 1992c.
[d] Annual SLEVs was estimated assuming that incinerator would be operating 250 hours/year (one burn/day, 5 days/week, and 50 weeks/year), according to EPA 1992f.
Dispersion Analysis Results:
[e] 5 years of meteorological data were used in the dispersion modeling analysis. The highest annual concentration of 0.36 $\mu g/m^3$ was found to occur during 1991.

TABLE F.—*Annual Emission Rates of the Criteria Pollutants from TA–16 Incinerator Burning HE-Contaminated Oil*

NO.	CRITERIA AIR POLLUTANTS	AMOUNT OF OILS BURNED ON AN ANNUAL BASIS[a]	EPA'S AP–42 EMISSION FACTORS[b]	ANNUAL EMISSION RATE[c]	
		lb/year	lb/gal.	lb/year	g/sec

Source Term Parameters:
Source term parameters obtained from incinerator specification were as follows:

- Incinerator stack height above ground level is 8.58 m.
- Stack inner diameter is 0.559 m.
- Stack exit velocity is 7 m/sec (assumed).
- Stack exit temperature is 427°C (assumed).
- Stack location is southeast corner of Building 1409 of TA–16.

Notes:
Annual Emission Rate:
[a] As presented in Table F, item 3.
Dispersion Analysis Results:
[b] 5 years of meteorological data (1991 to 1995) were used in the dispersion modeling analysis. The highest ISC–3 estimated annual concentration (C^{an}) was found to occur during 1991.

ATTACHMENT 12
AIR QUALITY IMPACT ASSESSMENT OF OPEN BURNING OPERATIONS AT HIGH EXPLOSIVES TREATMENT AND DISPOSAL FACILITY

Technical Area: TA–16

Emission Source: Open Burning Operations at High Explosives Treatment and Disposal Facility

There are three open burning emission sources at the High Explosive Processing Facilities (HEPF). These are all located at TA–16, High Explosives Treatment and Disposal Facility, and include the open burning of HE-contaminated solvents and oil, the open burning of scrap HE, and the flashing of HE-contaminated materials that cannot be burned.

Open Burning of HE-Contaminated Solvents and Oil at the Burn Pit Located at TA–16–394

Pollutant(s) Considered

There are two groups of emissions from open-burning operations of solvents and oil. These include toxic pollutants specified as volatile organics/hazardous air pollutants (VOC/HAP), and criteria pollutants—primarily carbon monoxide and PM_{10}. There are no significant NO_x emissions as a result of these activities because the relatively low temperatures associated with open burning suppress emissions of NO_x.

According to Tewerson (1985), some of the highly volatile chemicals associated with the burning solvents or oil include acetone, cyclohexane, ethanol, ethyl acetate, methyl alcohol, methyl ethyl ketone, butyl acetate, and toluene. These chemicals were therefore selected for evaluation.

Emission Rates of Pollutants Considered

Appropriate emission factors and fuel constituents were obtained from Tewerson (1985). The maximum amount of solvents and oil in a burn of 300 gallons (1,135.62 liters) and 1,200 gallons (4,542.48 liters) per year, respectively, was obtained from site data. Based on these values, the density of the fuel, and the assumption that the facility will operate 50 hours per year, an hourly emission rates of toxic and criteria air pollutants were estimated. They are presented in Tables A and B, respectively.

Major Assumptions

- 50 hours of burn operations a year (50 burns per year at 1-hour length of burn.
- Content of fine particulates (less than 10 micrometers in size) is 50 percent of the total particulate matter content.
- Emissions were modeled as surface-based volume sources using the EPA's ISC–3 Model with initial dispersion parameters estimated based on approximate burn tray dimensions.

- Following the conservative technique used for estimating short-term impacts from all emission sources, all fence line receptor locations, regardless of whether the public has access to these locations, were considered.
- Actual receptors will be considered for those sources where potential air quality impacts are likely to occur.

Results

Toxic Air Pollutants. Analysis of short-term (8-hour) impacts of the individual components comprising VOC/HAP emissions were considered at nearby fence line receptors. The analysis shows no impacts on ambient air quality; the SLEV/Q^h ratios are all greater than one (Tables C and D). That is, the estimated pollutant levels are below the established Guideline Values (GVs).

Criteria Air Pollutants. Two analyses were performed to estimate 8-hour SLEVs from open burning of HE-contaminated solvents and oil at the burn pit at TA–16–394.

Because potential impacts were predicted at all fence line receptors, including locations to which the public does not have access, the locations where the public does have access were considered. These locations are along the south border of TA–16 near State Road 4, bordering Bandelier National Monument, at 5,905.8 to 6,562 feet (1,800 to 2,000 meters) from the emission source. At these locations, the estimated 8-hour SLEV/Q^h ratios were all greater than one (Tables E and F).

Annual impacts of criteria pollutants from open burning of HE-contaminated solvents and oil at the burn pit at TA–16–394 were not considered due to the fact that the annual estimated emission rates (Tewerson 1985, Tables E and F) were too small to cause impacts.

Open Burning of Scrap HE at the Burn Pit Located at TA–16–388

Pollutant(s) Considered

The chemical constituents were selected for analysis based on information provided by Carter (1978). Due to uncertainty in identifying these constituents and their amounts in the scrap HE, chemicals of different toxicities were selected to represent the range of toxic emissions that may be emitted. These include hydrogen chloride, hydrogen fluoride, ammonia, ethanol, methyl alcohol, and acetylene.

Emission Rates of Pollutants Considered

Appropriate emission factors for selected VOC/HAP constituents were obtained from Table 3-5 of a document entitled "Air Emissions from Burning of Explosives" (Carter 1978). The maximum total amount of scrap HE burned per year, 106,526 pounds (48,320 kilograms), and the total estimated amount of VOC/HAP emissions per year (257 pounds [116.57 kilograms]) were obtained from site data. In order to estimate emissions associated with the burning of individual VOC/HAP components, it was assumed that the content of explosive components in scrap material is 1 percent. The major combustible components in scrap that account for at least 90 percent of composition are usually lumber or wood pallets. Estimated hourly and annual emission rates of toxic VOC/HAP pollutants, with the corresponding emission factors, are presented in Table G.

Major Assumptions

- The same assumptions that were used in the analysis of open-burning HE-contaminated solvents and oil at the Burn Pit Located at TA–16–394 are also made for this analysis.
- The content of explosive components in scrap material is 1 percent by weight.
- Emissions would be released over 8,760 hours of operations per year.

Results

Toxic Air Pollutants. Two analyses were performed to estimate 8-hour SLEVs of the toxic pollutants from open burning of scrap HE. Because potential impacts were predicted at fence line receptors to which the public does not have access, the locations where the public does have access were considered. The highest estimated 8-hour SLEV/Q ratios at receptor locations along the south border of TA–16 near State Road 4, bordering Bandelier National Monument, were found to be greater than one for all pollutants considered (Table H). That is, the estimated pollutant levels are below the established GV.

Annual impact analysis of toxic air pollutants from burning of HE scrap was performed at the sensitive receptor locations. Two toxic air pollutants for which inhalation reference concentrations (RfC) have been established were considered: hydrogen chloride and ammonia. The SLEV/Q^{an} ratios were found to be greater than 1 for these toxic air pollutants (Table I). That is, the estimated pollutant levels are below the established GV. None of the releases of toxic pollutants would result in air quality impacts.

Criteria Pollutants. The same methodology that was used to estimate potential annual impact of the toxic air pollutants was utilized to evaluate annual impacts of criteria pollutants. Three criteria pollutants were considered in the analysis, PM_{10}, CO, and NO_2. Annual emission rates for these pollutants were obtained directly from site data. The NAAQS/Q^{an} ratios were greater than one for all pollutants (Table J). That is, the estimated pollutant levels are below the NAAQS.

Annual impacts of criteria pollutants from the flashing of unburnable HE-contaminated materials were not considered because the quantities of emissions from these operations on an annual basis are much smaller than those from scrap HE-burning operations, and were too small to cause any impacts.

	Total							**0.4693**		**0.7673**

Emission Source:
Open burning of HE-contaminated solvents was considered at the pit located at TA–16–394.
Notes:
Hourly Emission Rate:
[a] Hourly emission rates in pounds per hour of each compound from burning fuel constituents were estimated using applicable emission factors, fuel constituents, and its amount in a burn.
[b] The maximum amount of solvents in a burn of 300 gallons per year was obtained from Tewerson 1985.
[c] Yield of compound is expressed in lb/lb of material combusted (Carter 1978).
Major Assumptions:
[d] 50 hours of burn operations a year (50 burns per year at 1 hour length of burn), according to Carter 1978.
[e] Content of fine particles PM_{10} (less than 10 micrometers in size) is 50% of the total particulate matter content.

TABLE B.—*Emissions of HE-Contaminated Oil from Open Burning at TA–16*

NO.	FUEL CON-STITUENTS	AMOUNT OF SOLVENTS BURNED[b,d]		AMOUNT OF FUEL CONSTITUENTS IN BURN	TOXIC POLLUTANTS		CRITERIA POLLUTANTS: CARBON MONOXIDE		CRITERIA POLLUTANTS: PARTICULATE MATTER (PM_{10})[e]

	Total							**1.8772**		**3.0690**

Emission Source:
Open burning of HE-contaminated solvents was considered at the pit located at TA–16–394.
Notes:
Hourly Emission Rate:
[a] Hourly emission rates in pounds per hour of each compound from burning fuel constituents were estimated using applicable emission factors, fuel constituents, and its amount in a burn.
[b] The maximum amount of solvents in a burn of 300 gallons per year was obtained from Tewerson 1985.
[c] Yield of compound is expressed in lb/lb of material combusted (Carter 1978).
Major Assumptions:
[d] 50 hours of burn operations a year (50 burns per year at 1 hour length of burn), according to Carter 1978.
[e] Content of fine particles PM_{10} (less than 10 micrometers in size) is 50% of the total particulate matter content.

TABLE C.—*8-Hour SLEV/Q Ratios of the Toxic Air Pollutants from Open Burning of HE-Contaminated Solvents at TA–16*

NO.	TOXIC AIR POLLUTANTS	CAS NUMBER	OEL[c]	1/100 OF THE OEL[d]	8-HOUR SLEV[b]		ESTIMATED HOURLY EMISSION RATE[a] (Q^h)	SLEV/Q^h RATIO

8	Toluene	108-88-3	188,000	1,880	4.11E+00	3.26E+01	0.5797	5.62E+01

Emission Source:
Open burning of HE-contaminated solvents was considered at the pit located at TA–16–394.
Notes:
Major Assumptions:
[a] Emission rates are presented in Table A. Emissions were modeled as surface-based volume source using EPA's ISC–3 Model with initial dispersion parameters estimated based on approximate tray dimensions. Initial lateral and vertical dimensions of the volume source was estimated based on the EPA Guideline, "Volume Source Inputs," EPA's User's Guide for the Industrial Source Complex (ISC–3) Dispersion Model, Volume 1 (EPA 1992b).
Dispersion Analysis Results:
[b] The highest ISC–3 estimated concentration at fence line receptors was found to be 457.9 μg/m³ when emission rate is 1 g/sec.
Guideline Values
[c] OEL = occupational exposure limits established by the American Conference of Governmental Industrial Hygienists (ACGIH 1997).
[d] 1/100 of the OEL is 8-hour guideline value used in the analysis to estimate short-term (8-hour) impacts of the toxic air pollutants.

TABLE D.—*8-Hour SLEV/Q Ratios of the Toxic Air Pollutants from Open Burning of HE-Contaminated Oil at TA–16*

NO.	TOXIC AIR POLLUTANTS	CAS NUMBER	OEL[c]	1/100 OF THE OEL[d]	8-HOUR SLEV[b]		ESTIMATED HOURLY EMISSION RATE[a] (Q^h)	SLEV/Q^h RATIO

8	Toluene	108-88-3	188,000	1,880	4.11E+00	3.26E+01	2.3187	1.41E+01

Emission Source:
Open burning of HE-contaminated oil was considered at the pit located at TA–16–394.
Notes:
Major Assumptions:
[a] Emission rates are presented in Table B. Emissions were modeled as surface-based volume source using EPA's ISC–3 Model with initial dispersion parameters estimated based on approximate tray dimensions. Initial lateral and vertical dimensions of the volume source was estimated based on the EPA Guideline, "Volume Source Inputs," EPA's User's Guide for the Industrial Source Complex (ISC–3) Dispersion Model, Volume 1 (EPA 1992b).
Dispersion Analysis Results:
[b] The highest ISC–3 estimated concentration at fence line receptors was found to be 457.9 μg/m^3 when emission rate is 1 g/sec.
Guideline Values
[c] OEL = occupational exposure limits established by the American Conference of Governmental Industrial Hygienists (ACGIH 1997).
[d] 1/100 of the OEL is 8-hour guideline value used in the analysis to estimate short-term (8-hour) impacts of the toxic air pollutants.

TABLE E.—*8-Hour SLEV/Q Ratios of the Criteria Pollutants from Open Burning of HE-Contaminated Solvents at TA–16*

NO.	CRITERIA AIR POLLUTANTS[a]	CAS NUMBER	OEL[d]	1/100 OF THE OEL[e]	8-HOUR SLEV[c]		ESTIMATED HOURLY EMISSION RATE[b] (Q^h)	SLEV/Q^h RATIO
			μg/m³	μg/m³	g/sec	lb/hr	lb/hr	
1	**2**	**3**	**4**	**5**	**6**	**7**	**8**	**9**
1	Particulate Matter (PM_{10})	NA	3,000	30	3.65	29.0	0.77	37.8
2	Carbon Monoxide	630-08-0	29,000	290	35.3	280.0	0.47	597.0

Emission Source:

Open burning of HE-contaminated oil was considered at the pit located at TA–16–394.

Notes:

Major Assumptions:

[a] The same modeling procedure that was used to estimate the air quality impacts of toxic air pollutants was applied to criteria pollutants that have the potential to be released from open burning operations at TA–16 under future alternatives. Two criteria pollutants (CO and PM_{10}) were considered from open burning operations of HE-contaminated oil at the burn pit located at TA–16–394. According to Tewerson 1985, there is no significant NO_x emissions as a result of these activities.

[b] Emission rates are presented in Table A. Emissions were modeled as surface-based volume source using EPA's ISC–3 Model with initial dispersion parameters estimated based on approximate tray dimensions. Initial lateral and vertical dimensions of the volume source was estimated based on the EPA Guideline, "Volume Source Inputs," EPA's User's Guide for the Industrial Source Complex (ISC–3), Dispersion Model, Volume 1 (EPA 1992b).

Dispersion Analysis Results:

[c] In this analysis, receptor locations to where the public could have access were considered. These are locations along the south border of TA–16 near State Road 4, bordering Bandelier National Monument. The highest ISC–3 estimated concentration at these receptor locations was found to be 8.2 μg/m³ when emission rate is 1 g/sec.

Guideline Values

[d] OEL = occupational exposure limits established by the American Conference of Governmental Industrial Hygienists (ACGIH 1997).

[e] 1/100 of the OEL is 8-hour guideline value used in the analysis to estimate short-term (8-hour) impacts of the toxic air pollutants.

NA = Not applicable

TABLE G.—*VOC/HAP Emissions from Open Burning of Scrap HE at TA–16*

NO.	CONSTITUENTS[d]	AMOUNT OF SCRAP HE BURNED PER YEAR[c]	AMOUNT OF EXPLOSIVE COMPONENTS IN A BURN PRODUCING VOC/HAP[d,e]		EMISSION FACTORS[b]	VOC/HAP POLLUTANTS	
						ANNUAL EMISSION RATE[a]	HOURLY EMISSION RATE[a,f]
		kg/year	lb/year	tons/year	lb/ton	lb/year	lb/hr
1	**2**	**3**	**4**	**5**	**6**	**7**	**8**
1	Hydrogen Chloride	48,320	1,065	0.5	22.9	12.2	0.24
2	Hydrogen Fluoride	48,320	1,065	0.5	30.0	16.0	0.32
3	Ammonia	48,320	1,065	0.5	23.9	12.7	0.25
4	Ethanol	48,320	1,065	0.5	160.0	85.2	1.70
5	Methyl Alcohol	48,320	1,065	0.5	99.0	52.7	1.05
6	Acetylene	48,320	1,065	0.5	146.0	77.8	1.56
	Total					257	

Emission Source:
Open burning of scrap HE was considered at the pit located at TA–16–388.
Notes:
Annual and Hourly Emission Rates:
[a] Annual and hourly emission rates of each compound from burning scrap were estimated using applicable emission factors, scrap constituents, and their amount in scrap.
[b] Emission factors in lb/ton for the VOC/HAP constituents were obtained from Table 3–5 entitled, "Air Emissions From Burning of Explosives" (Carter 1978).
[c] The maximum total amount of scrap HE burned per year (48,320 kilograms) and the total estimated amount of VOC/HAP emissions per year (257 pounds) was obtained from Table G of Tewerson 1985.
Major Assumptions:
[d] Constituents of VOC/HAP emissions were selected based on Carter 1978. Due to uncertainty in identifying of typical composition of explosives and their amount in the scrap HE, chemicals of different toxicity were selected to represent the range of toxic emissions that may be emitted.
[e] The content of explosive components in scrap is 1% by weight.
[f] 50 hours of burn operations a year (50 burns per year at 1 hour length of burn).
VOC/HAP = volatile organic compound/hazardous air pollutant

TABLE H.—*8-Hour SLEV/Q Ratios of the Toxic Air Pollutants from Open Burning of Scrap HE at TA–16*

NO.	TOXIC AIR POLLUTANTS	CAS NUMBER	OEL[d]	1/100 OF THE OEL[e]	8-HOUR SLEV[b,c]		ESTIMATED HOURLY EMISSION RATE[a] (Q^h)	SLEV/Q^h RATIO

6	Methyl Alcohol	67-56-1	262,000	2,620	5.38E+01	4.27E+02	1.05	4.06E+02

Emission Source:
Open burning of scrap HE was considered at the pit located at TA–16–388.
Notes:
Major Assumptions:
[a] Emission rates are presented in Table G. Emissions were modeled as surface-based volume source using EPA's ISC–3 Model with initial dispersion parameters estimated based on approximate tray dimensions. Initial lateral and vertical dimensions of the volume source was estimated based on the EPA Guideline, "Volume Source Inputs," EPA's User's Guide for the Industrial Source Complex (ISC–3) Dispersion Model, Volume 1 (EPA 1992b)
Dispersion Analysis Results:
[b] In this analysis, receptor locations where the public could have access to were considered. These are locations along the south border of TA–16 near State Road 4, bordering Bandelier National Monument.
[c] The highest ISC–3 estimated concentration at fence line receptors was found to be 48.7 μg/m³ when emission rate is 1 g/sec.
Guideline Values
[d] OEL = occupational exposure limits established by the American Conference of Governmental Industrial Hygienists (ACGIH 1997).
[e] 1/100 of the OEL is 8-hour guideline value used in the analysis to estimate short-term (8-hour) impacts of the toxic air pollutants.

TABLE I.—*Annual SLEV/Q Ratios of the Toxic Air Pollutants from Open Burning of Scrap HE at TA–16*

NO.	TOXIC AIR POLLUTANTS	CAS NUMBER	RfC[c]	ANNUAL SLEVs[b]		ESTIMATED ANNUAL EMISSION RATE[a] (Q[a])	SLEV/Q[a] RATIO
			μg/m³	g/sec	lb/year	lb/year	
1	2	3	4	5	6	7	8
1	Ammonia	7664-41-7	100	1.30E+02	5.14E+04	12.7	4.05E+03
2	Hydrogen Chloride	7647-01-0	20	2.59E+01	1.03E+04	12.2	8.43E+02

Emission Source:
Open burning of scrap HE was considered at the pit located at TA–16–388.
Notes:
Major Assumptions:
[a] Emission rates are presented in Table G. Emissions were modeled as surface-based volume source using EPA's ISC–3 Model with an initial dispersion parameters estimated based on an approximate tray dimensions. Initial lateral and vertical dimensions of the volume source was estimated based on the EPA Guideline, "Volume Source Inputs," EPA's User's Guide for the Industrial Source Complex (ISC–3) Dispersion Model, Volume 1 (EPA 1992b).
Dispersion Analysis Results:
[b] The ISC–3 estimated annual concentration used to compute annual SLEV was found to be 0.77 μg/m^3 at sensitive receptors when emission rate is 1 g/sec.
Guideline Value(s):
[c] RfC = Inhalation reference concentrations that represent the annual guideline value(s) used in the analysis to estimate annual impacts of the toxic air pollutants.

TABLE J.—*Annual SLEV/Q Ratios of the Toxic Air Pollutants from Open Burning of Scrap HE at TA–16*

Guideline Value(s):
[c] RfC = Inhalation reference concentrations that represent the annual guideline value(s) used in the analysis to estimate annual impacts of the toxic air pollutants.

TABLE K.—*Annual Impact Analysis of the Criteria Pollutants from Open Burning of Scrap HE at TA–16–388*

NO.	CRITERIA AIR POLLUTANTS	AVERAGING TIME PERIOD	ANNUAL EMISSION RATE[a,c]	ICS–3 ESTIMATED ANNUAL POLLUTANT CONCENTRATION (C^{an})[b,d]	NATIONAL (NAAQS)	(NAAQS)/(C^{an}) RATIO
			g/sec	μg/m³	μg/m³	
1	2	3	4	5	6	7
1	Particulate Matter (PM_{10})	Annual	9.66E-02	7.49E-02	50	6.68E+02
2	Nitrogen Oxide	Annual	9.68E-02	7.50E-02	100	1.33E+03
3	Carbon Monoxide	Annual	3.73E-02	2.89E-02	80	2.77E+03

Emission Source:
Open burning of scrap HE was considered at the pit located at TA–16–388.
Notes:
Major Assumptions:
[a] Annual emission rates were estimated based on information provided in Table G of Tewerson 1985.
[b] Emissions were modeled as surface-based volume source using EPA's ISC–3 Model with initial dispersion parameters estimated based on approximate tray dimensions. Initial lateral and vertical dimensions of the volume source was estimated based on the EPA Guideline, "Volume Source Inputs," EPA's User's Guide for the Industrial Source Complex (ISC–3) Dispersion Model, Volume 1 (EPA 1992b).
[c] Emissions would be released over 8,760 hours of operations per year.
Dispersion Analysis Results:
[d] 5 years of meteorological data (1991 to 1995) were used in the dispersion modeling analysis. The highest ISC–3 estimated annual concentration (C^{an}) was found to occur during 1991.

ATTACHMENT 13
AIR QUALITY IMPACT ASSESSMENT OF EMISSIONS FROM FIRING SITES

Technical Area(s): TA–14, TA–15, TA–36, TA–39, and TA–40 of the High Explosives Firing Sites (HEFSs)

Emission Sources Detonation of High Explosives at HEFSs Testing Sites

Hydrodynamic experiments involving the detonation of high explosives are conducted at several areas within TA–14, TA–15, TA–36, TA–39, and TA–40. These experiments are used to gain information on the physical properties and dynamic behavior of materials used in nuclear weapons and to evaluate the effects of aging on the nuclear weapons remaining in stockpile. HEFSs combine the capability of testing explosives with the ability to evaluate explosion dynamics.

<u>Screening Analysis</u>

Pollutant(s) Considered

There are up to eight metals that may be emitted into the atmosphere in respirable form during HEFSs testing operations. These include depleted uranium, beryllium, lead, aluminum, copper, tantalum, tungsten, and iron. Two of these TAs (TA–15 and TA–36) have the potential to emit all of these metals; TA–39 may emit all of these metals with the exception of depleted uranium; TA–40 may emit aluminum, copper, tantalum, tungsten, and iron; and TA–14 may emit depleted uranium and lead.

Three of the metals that may be emitted from HEFSs operations, beryllium, lead, and depleted uranium, are highly toxic. The 8-hour Guideline Values (GVs) developed for these pollutants are 0.02 microgram per cubic meter, 0.5 microgram per cubic meter, and 2 micrograms per cubic meter, respectively. The toxicity of depleted uranium is assumed to be the same as for a natural uranium. The other pollutants, copper, tungsten, tantalum, and iron, are moderately toxic, with 8-hour GVs between 10 micrograms per cubic meter and 50 micrograms per cubic meter.

These pollutants were all considered in the air quality impacts analysis. Lithium hydride, another toxic pollutant released from HEFSs operations, was not considered because it is highly reactive and undergoes rapid chemical transformation to lithium hydroxide, which has a very low vapor pressure and no OEL.

Emission Rates of Pollutants Considered

Total amounts of material that are expected to be used for HEFSs activities at each TA, together with the maximum annual and 8-hour respirable release rates were estimated from site operations data. Annual release rates were estimated using the assumption that the release fractions are 10 percent of the total material exploded. The 8-hour release rates of respirable particles were estimated using a scale factor of 0.085. That is, the 8-hour release was estimated by multiplying annual respirable emission rate by a factor of 0.085. This factor was derived from a consideration of the number of tests per year and the range in amount of material per shot, in order to best represent a release of this duration. The 8-hour emission rate is needed for a comparison with the appropriate SLEV.

Estimated emission rates of pollutants used in the dispersion modeling analysis for each TA are presented in Table A.

Dispersion Modeling Analysis

EPA's Puff Model

Total amount of materials released at each TA during HEFSs operations were modeled using the EPA's Puff Model.

Included in the EPA's TSCREEN Model, the Puff Model is designed to assess the impacts of toxic air pollutants from instantaneous releases. The model is applicable if the travel time to the receptor from the source exceeds the release duration and if the release duration is less than the averaging time of interest to the user.

It is assumed that a HEFSs explosion in the atmosphere reasonably simulates an instantaneous release, where all mass is released in less that 1 to 5 minutes.

The Puff Model conservatively uses worst-case meteorological conditions to determine the maximum concentrations at receptors located directly downwind under the plume centerline. The meteorological conditions that result in a maximum concentration at each of the downwind distances are usually a wind speed of 9.1×10^{-4} feet per second (1 meter per second), a low mixing height (984.24 to 1,640.40 feet [300 to 500 meters]), and stable atmospheric conditions.

The Puff Model assumes that all materials (emissions) are released during a very short period of time (i.e., 1 to 5 minutes), with zero emissions the rest of the averaging time. If the release duration is less than the selected averaging time, the model calculates a concentration reduction based on ratio of the duration time to the averaging time. That is, the estimated maximum instantaneous concentration is converted internally by the model to average 1-minute, 5-minute, 15-minute, and 60-minute concentrations. For this analysis, 60-minute concentrations were estimated and these values were then converted to 8-hour values using a factor 0.125.

Model Inputs Used in the Dispersion Analysis

- The total amount of material released projected from the index for this operation
- The initial dispersion parameters were Y = 76.11 feet (23.2 meters) for lateral dispersion and Z = 30.18 feet (9.2 meters) for vertical dispersion
- The downwind distances to the receptor locations were as follows:
  - TA–14: 7,496.63 feet (2,285 meters)
  - TA–15: 4,494.70 feet (1,370 meters)
  - TA–36: 1,640.40 feet (500 meters)

— TA–39: 3,001.93 feet (915 meters)
— TA–40: 4,215.83 feet (1,285 meters)

- Ground level release

Estimated emission rates of the pollutants are summarized in Table A.

Results

Estimated 8-hour pollutant concentrations ($C^{8\text{-hr}}$) were compared with the project's 8-hour GVs, 1/100 of the OEL, for each pollutant. Results of the analysis are presented in Table B.

The $GV/C^{8\text{-hr}}$ ratios are less than one (i.e., the estimated concentration of a pollutants is greater than its GV) for the following releases:

- Depleted uranium, beryllium, lead, aluminum, copper, tantalum, tungsten, and iron from TA–15
- Depleted uranium, beryllium, lead, copper, and iron from TA–36
- Beryllium, lead, aluminum, and copper from TA–39
- Depleted uranium and lead from TA–14
- Copper from TA–40

Based on the ratios, depleted uranium, beryllium, and lead are of particular concern. Additional information for a health risk analysis was therefore provided in a further analysis. Due to the fact that all releases from firing operations are short-term, the releases of these pollutants were not considered in the additive impact analysis, which is associated with long-term exposure.

<u>Detailed Analysis</u>

Detailed dispersion modeling was done for HEFSs for the pollutants that exceeded the short-term GVs using the screening analysis. This modeling was conducted using a combination of HOTSPOT 8.0 model and the ISCST3 model. HOTSPOT was used to calculate the effective release height and lateral and vertical dimensions of the volume. These calculated values were used in the ISCST3 modeling, which was run as a volume source model.

Modeling Assumptions

- Amount considered for each test = 154 pounds (70 kilograms)
- Using HOTSPOT, cloud top was calculated
- Cloud top = 76 $(w)^{0.25}$, where w is in pounds, and cloud top height is in meters
- Cloud top for 154-pound (70-kilogram) HE detonation = 76 $(154 \text{ pounds})^{0.25}$ = 878.3 feet (267.7 meters)
- Cloud radius = 0.2 x cloud top height
- Cloud radius = 0.2 x 267.7 meters
  = 175.7 feet (53.54 meters)
- Effective release height = 0.6 (76) $(w)^{0.25}$

- Effective release height = 0.6 (76) $(w)^{0.25}$
  = 0.6 x 267.7 meters
  = 524.9 feet (160 meters)
- Lateral dimension of the volume in meters, σ_y = 0.5 x cloud radius
- Vertical dimension of the volume in meters, σ_z= 0.2 x cloud top
- Lateral dimension of the volume in meters, σ_y = 0.5 x 53.54
  = 87.8 feet (26.77 meters)
- Vertical dimension of the volume in meters, σ_z= 0.2 x cloud top
  = 0.2 x 267.7
  = 175.7 feet (53.54 meters)

Emission Sources Modeled

TA	BERYLLIUM (Be)	DEPLETED URANIUM (DU)	LEAD (Pb)
TA–14	—	X	X
TA–15	X	X	X
TA–36	X	X	X
TA–39	X	—	X

Both the Expanded Operations and the No Action Alternatives were modeled.

Modeled Emission Rates—Expanded Operations Alternative

SOURCE NUMBER	POLLUTANT	ANNUAL RESPIRABLE EMISSION RATE (kg/yr)	HOURLY MODELED EMISSION RATE (g/sec)
TA–14	Depleted Uranium	3.1	0.0001
	Lead	3.1	0.0001
TA–15	Beryllium	3.0	0.0001
	Depleted Uranium	270.0	0.0086
	Lead	15.0	0.0005
TA–36	Beryllium	3.0	0.0001
	Depleted Uranium	120.0	0.0038
	Lead	3.0	0.0001
TA–39	Beryllium	3.0	0.0001
	Lead	3.0	0.0001

The No Action Alternative emission rates are one-third of the Expanded Operations Alternative emission rates. Therefore, modeling for the No Action Alternative was done using one-third of the emission rates stated in the above table.

Location of Sources and Receptors Modeled

SOURCES AND RECEPTORS	STATE PLANE COORDINATES, EAST (ft)	STATE PLANE COORDINATES, NORTH (ft)
TA–14	1,620,310	1,763,740

Notes:
Emission Sources:
[a] Firing operations involve detonations of explosives at TA–14, TA–15, TA–36, TA–39, and TA–40. Particulate emissions released into the atmosphere due to detonation of high explosives contain bonded metal emissions in respirable form.
Emission Rates of Pollutants Considered:
[b] The maximum amount of material that will be used during testing operations and the estimated maximum annual respirable release rates (in kilograms per year per TA) were obtained from Table B for TA–14, Table D for TA–15, Table E for TA–36, Table H for TA–39, and Table J for TA–40 of EPA 1992c. Respirable release rates were estimated based on the assumption that this fraction is 10% of total amount of material exploded.
[c] The total 8-hour respirable release rates (in kilograms), as a results of these operations, were estimated using the scale factor of 0.085.
Major Assumptions:
Lithium hydride was not considered because it is highly reactive and undergoes chemical transformations to lithium hydroxide that has very low vapor pressure and no OEL.
Dispersion Analysis:
[d] The total amount of material released, in grams, was used in dispersion analysis to estimate maximum 1-hour average concentration at specified receptor locations. Each release was modeled using the EPA's Puff Model as an instantaneous release.
[e] These quantities are dominated by the support structures constructed for tests. These structures, in actuality, are not expended in explosive tests and do not contribute to test air emissions.

Notes:
Emission Sources:
[a] Firing operations involve detonations of explosives at TA–14, TA–15, TA–36, TA–39, and TA–40. Particulate emissions released into the atmosphere due to detonation of high explosives contain bounded metal emissions in respirable form.
Emission Rates of Pollutants Considered:
[b] Emission rates of pollutants are from Table A.
Major Assumptions:
[c] Estimated 1-hour average concentrations was converted to 8-hour concentrations using a conversion factor of 0.125.
Dispersion Analysis:
[d] Total amounts of material released at each TA over 8-hour period were modeled using the EPA's PUFF Model as an instantaneous release scenario with assumed initial dispersion parameters. The lateral dispersion parameter (sigma Y) was assumed to be 23.2 meters; the vertical dispersion parameter (sigma Z) was assumed to be 9.2 meters.
[e] The conditions that produced the maximum concentrations at each of the downwind distances were: wind speed of 1 m/sec; mixing height of 320 meters; and stable atmospheric conditions.
[f] The downwind distances at which off-site concentrations were estimated were selected on TA by TA basis. These distances are as follows: TA–14, 2,285 meters; TA–15, 1,370 meters; TA–36, 500 meters; TA–39, 915 meters; and TA–40, 1,285 meters.

ATTACHMENT 14
AIR QUALITY IMPACT ASSESSMENT OF THE HEALTH RESEARCH LABORATORY (TA–43) EMISSIONS

Technical Area: TA–43

Emission Source(s)

There are four emission exhaust ducts located on the roof of the Health Research Laboratory (HRL) that emit carcinogenic pollutants from HRL operations. The pollutants of concern for this analysis are chloroform, trichloroethylene, methylene chloride, formaldehyde, and acrylamide.

The releases of pollutants may potentially impact nearby sensitive receptors (such as air intake shafts and/or operable windows) at the LANL Medical Center located in close proximity to HRL. Numerous receptor locations along the face and roof of the hospital were considered. Closest to HRL exhaust duct is an air intake shaft (#1) located within distance of 328 feet (100 meters) of stack B247 on the roof of the HRL.

Source Term Parameters

Annual pollutant emission rates were estimated were those projected for the Expanded Operations Alternative. Associated stack parameters and locations are presented in Table A. It was assumed that annual emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA's ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings, including the Medical Center and HRL Building 1, within the zone of the stack plume influence were considered in the downwash analysis.

The highest annual average concentrations of these pollutants were found at the elevated receptors of the Medical Center. These values were then used to estimate the incremental cancer risk of these releases using appropriate unit risk factors.

Results

Results of the analysis are presented in Tables B and C. As shown in Table C, four of the five pollutants considered (chloroform, trichloroethylene, formaldehyde, and acrylamide) have the estimated maximum cancer risk values greater than Guideline Value of 1.0×10^{-8}.

The maximum annual concentration of 3.04×10^{-2} micrograms per cubic meter was estimated for chloroform, the most critical of these carcinogens, at one of the air intake shaft of the Medical Center located at a height of 40 feet (12.2 meters) above the ground level (Refer to the Receptor #175 of the LANL sensitive receptors). The maximum cancer risk of chloroform is estimated to be 6.99×10^{-7} at this location, and sum of the cancer risks of all of these carcinogens combined is estimated to be 7.79×10^{-7}. These pollutants were further evaluated as a part of the additive impact analysis.

ATTACHMENT 15
AIR QUALITY IMPACT ASSESSMENT OF THE TA–53 CHLOROFORM EMISSIONS

Technical Area: TA–53, Building MPF–15

Emission Source(s)

Chloroform is used for cleaning in preparation for surface chemistry studies using the LANSCE neutron beam. All of the chloroform used evaporates during this process.

There are two emission sources of the chloroform emissions at TA–53; both are located on Building MPF–15. One emission source is an exhaust duct from the clean room and the other is an exhaust duct from chemistry laboratory.

Source Term Parameters

Stack parameters and their locations are provided in Table A.

Emission Rates of Pollutants Considered

Estimated annual emission rates of chloroform from the two emission sources are shown in Table A. All chloroform used is assumed released into the atmosphere. It was assumed that emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA's ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings within the zone of stack plume influence were considered in the downwash analysis. The highest annual concentration estimated by the ISC–3 Model (Table B) was used to estimate the maximum cancer risk of chloroform releases using its unit risk factor.

Results

Results of the analysis are presented in Tables B and C. As shown in Table C, the maximum combined cancer risk associated with releases of chloroform from two emission sources on building MPF–15 of the TA–53 facility is 1.29×10^{-8}, which is above the Guideline Value of 1.0×10^{-8}. This pollutant was, therefore, further evaluated as part of the additive impact analysis.

ATTACHMENT 16
AIR QUALITY IMPACT ASSESSMENT OF THE TA–55 BERYLLIUM EMISSIONS

Technical Area: TA–55, Building PF–4

Emission Source(s)

There are two beryllium emission sources at TA–55, located on Building PF–4, TA–55 FE–15 and TA–55 FE–16.

Source Term Parameters

Stack parameters and their locations are shown in Table A.

Emission Rates of Pollutants Considered

Annual emission rates of the beryllium were estimated based on the existing permit application for TA–55. Emissions from these sources are released to the atmosphere through a HEPA filtration system, with a removal efficiency of 99.95 percent. Controlled emission rates are estimated to be 3.0×10^{-3} pounds per year for TA–55 FE–15 and 4.2×10^{-3} pounds per year for TA–55 FE–16.

Estimated annual emission rates of the beryllium that were used in the analysis are shown in Table A. It was assumed that emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA's ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings within the zone of stack plume influence were considered in the downwash analysis. The highest annual concentration estimated by the ISC–3 Model (Table B) was used to compute the maximum combined cancer risk of beryllium releases using its unit risk factor.

Results

Results of the analysis are presented in Tables B and C. As shown in Table C, the combined cancer risk associated with releases of beryllium from emission sources on Building PF–4, TA–55 FE–15 and TA–55 FE–16, is 2.35×10^{-10}, which is below the Guideline Value of 1.0×10^{-8}.

ATTACHMENT 17
AIR QUALITY IMPACT ASSESSMENT OF THE TA–55 HYDROCHLORIC AND NITRIC ACID EMISSIONS

Technical Area: TA–55, Building PF–4, Stacks FE–15 and FE–16

Emission Source(s)

The chemistry group at TA–59 uses nitric and hydrochloric acids for the recovery of plutonium. There are few emission sources of hydrochloric and nitric acid at TA–55. The two sources that were considered in the analysis include stacks FE–15 and FE–16, located on Building PF–4.

Source Term Parameters

Stack parameters and their locations are provided in Table A.

Emission Rates of Pollutants Considered

Estimated maximum hourly emission rates of nitric acid and hydrochloric acids associated with stacks FE–15 and FE–16 that were used in the analysis are shown in Table A. It was assumed that emissions would be released over 8,760 hours of operation per year.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA's ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings within the zone of stack plume influence were considered in the downwash analysis.

The ISC–3-estimated 8-hour concentrations of nitric and hydrochloric acids are shown in Table B. Using these values and appropriate 8-hour Guideline Values (GVs), 8-hour SLEVs were estimated and compared to hourly emission rates of these pollutants.

Results

Results of the analysis are presented in Table C. As shown in Table C, the 8-hour concentrations of both hydrochloric acid and nitric acid are below the 8-hour GVs. Accordingly, 8-hour SLEV/Q ratios are all greater than one. That is, the estimated nitric acid and hydrochloric acid levels are below the applicable GVs.

ATTACHMENT 18
AIR QUALITY IMPACT ASSESSMENT OF THE TA–59 HYDROCHLORIC AND NITRIC ACIDS EMISSIONS

Technical Area: TA–59, Building 1

Emission Source(s)

The radio chemistry group at TA–59 uses large quantities of nitric and hydrochloric acid for the digestion and separation processes. One percent of each chemical is estimated to be released to the atmosphere due to container transfer.

There are two groups of emission sources of the hydrochloric and nitric acid at TA–59. They are both located on Building 1 and include exhaust fume hoods from laboratory rooms. One group of emission sources is associated with Hoods #102 through 106, and the other with Hoods #184 through 186. One representative stack with equivalent source parameters was used in the dispersion analysis for each group of these emissions sources.

Source Term Parameters

Stack parameters and their locations are provided in Table A.

Emission Rates of Pollutants Considered

Estimated maximum hourly emission rates of nitric acid and hydrochloric acids associated with two groups of emission sources that were used in the analysis are shown in Table A.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA's ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings within the zone of stack plume influence were considered in the downwash analysis.

Due to the fact that laboratory operating schedules are related to the daytime, the 8-hour concentration was computed for this time period. The highest daytime 8-hour concentration of hydrochloric and nitric acid was found to occur between 8:00 a.m. and 4:00 p.m. in 1991, at the receptor site located near boundary of TA–59 on Pajarito Road (Table B). These concentrations were compared to the appropriate 8-hour Guideline Values (GVs).

Results

Results of the analysis are presented in Table C. As shown in Table C, the 8-hour concentration of the nitric acid is above the 8-hour GV, and the 8-hour concentration of the hydrochloric acid is below the 8-hour GV. The results of the nitric acid analysis, therefore, were referred to the human health and ecological risk assessment process.

TABLE A.—*Stack Parameters and Emission Rate of the Hydrochloric and Nitric Acid Associated with Emission Sources of the TA–59 Building 1*

NO.	EMISSION SOURCE/ POLLUTANT[a]	STACK PARAMETERS					ESTIMATED MAXIMUM HOURLY EMISSION RATE	
		UTM COORD. (X; Y)	HEIGHT	AIRFLOW[b,c]	VELOCITY	DIAMETER		
		m	m	m^3/sec	m/sec	m	lb/hr	g/sec
1	TA–59 Rooms 102-106, Nitric Acid	381228; 3969886	18.29	8.73	14.06	0.89	5.00E+00	6.30E-01

4	TA–59 Rooms 184-186, Hydrogen Chloride	381218; 3969911	12.27	0.54	5.80	0.34	7.20E-01	9.07E-02

Notes:
[a] All emission sources associated with a fume hoods on Building 1 were divided into the two categories: emission sources from Room 102-106 and emission sources from Room 184-186. A representative stack from each group of emissions sources was used in the dispersion modeling analysis.
[b] Due to the fact that fume hoods in Rooms 102, 103, 104, and 106 are connected to the central exhaust system, the total airflow rate of 18,500 cubic feet per minute going through the central system was used to estimate the average flow rate associated with a first group of emission sources.
[c] The average airflow rate associated with fume hoods of the second group of emission sources was estimated using the actual flow rate of each hood.

TABLE B.—*ISC–3 Estimated 8-Hour Concentration of the Hydrochloric and Nitric Acid Associated with Emission Source of the TA–59 Building 1 Using 1991 to 1995 Meteorological Data*[a]

ATTACHMENT 19
AIR QUALITY IMPACT ASSESSMENT OF THE TA–53 OZONE EMISSIONS

Technical Area: TA–53, Building MPF–14

Emission Source(s)

Ozone is generated as a by-product from operation of the advanced free electron laser at TA–53. The source of ozone emissions is located at TA–53 Building MPF–14.

Source Term Parameters

Stack parameters, locations of emission sources, and the estimated maximum hourly emission rates of ozone are shown in Table A.

Dispersion Modeling Analysis

An air quality impacts analysis was conducted using EPA's ISC–3 Model and 5 years of on-site meteorological data. All nearby buildings within the zone of stack plume influence were considered in the downwash analysis.

The ISC–3-estimated 1-hour and 8-hour ozone concentrations are provided in Tables B and C, respectively. These values were compared with corresponding 1-hour National Ambient Air Quality Standards (NAAQS) ozone standard, and appropriate 8-hour Guideline Values (GVs).

Results

Results of the analysis are presented in Table D. As shown in Table D, the 1-hour and 8-hour ozone concentrations are below the applicable standards and GVs.

APPENDIX C
CONTAMINANT DATA SETS SUPPORTING ECOLOGICAL AND HUMAN HEALTH CONSEQUENCE ANALYSIS

Appendix C consists of nine statistical data tables constructed from databases maintained as part of LANL's Environmental Surveillance Program and Environmental Restoration (ER) Project. The tables include columns for: (1) the number of times for which the analyte was detected; (2) the number of times the analyte was sampled; (3) units; (4) the minimum, maximum, and arithmetic mean values; and (5) the 95 percent confidence limit (mean, plus two standard deviations). Only analytes that were detected at least once during the sampling period (1990 to 1996) are shown. Mean values and values for the 95 percent confidence interval are reported in exponential notation and rounded to two significant figures.

The NPDES table, Table C–1, consists of 1994 to 1996 data tabulated by the Water Quality and Hydrology Group (ESH–18) from laboratory inorganic trace analysis (CST–9) reports. The data are arranged by watershed.

Surface water and sediment tables, Tables C–2 through C–5, consist of environmental surveillance and compliance program data from the years 1991 through 1996, found in the LANL Environmental Surveillance Reports (e.g., *Environmental Surveillance at Los Alamos During 1995*, LANL 1996b). The data are arranged by location (on site, perimeter, and regional) and by watershed.

Groundwater tables, Tables C–6 and C–7, also consist of LANL environmental surveillance compliance program data from 1991 through 1996, found in the LANL Environmental Surveillance and Reports. The data are arranged by groundwater regime (alluvial, intermediate, and main) and by watershed (for alluvial and intermediate only).

Soils tables, Tables C–8 and C–9, consist of ER Project data. The data are arranged by both analyte and by watershed. Tables C–8 and C–9 in the Draft SWEIS contained incorrect data and these two tables have been completely reconstructed to eliminate these errors. These errors were a result of including data collected in the early phases of the ER Project that had not undergone quality assurance screening. These data contained known laboratory analytical errors, contained errors in unit conversions, and contained errors from samples contaminated either during sample collection or in the chemical laboratory during analysis. The problem occurred during data extraction because these samples with known problems were not screened. The corrected tables only use those data from the ER Project that have undergone quality assurance screening and are known to be error free.

Tables were constructed by first summing the total number of analyses for each analyte and reporting the number in the "Analyzed" column of each table. For radioactivity measurements, all zero and negative results were removed from the data set, and the remaining results were summed for each analyte and reported in the "Detected" column. Thus, for radionuclides, many results below the detection limit determined by the analytical laboratory are represented in the table as "Detects." For constituents other than radioactivity measurements, all non-detect results were removed from the data set, and the remaining results were summed for each analyte and reported in the "Detected" column. These detected results were used to calculate the minimum, mean, maximum, and 95 percent confidence limit. The detected results were not compared to either the detection limit for the analytical laboratory or the associated counting uncertainty for radionuclides. Thus, for radiochemical analyses of groundwater, surface water, and sediment, the detected results do not agree with LANL's Environmental Surveillance Program's definition of "detects" as results that are (1) greater than the detection limit and (2) equal to or greater than 4.66 times the counting uncertainty.

Because only positive "detects" were averaged, not the total number of samples analyzed, the number of "detects" is thus higher than reported in the LANL Environmental Surveillance Reports, and the mean and 95 percent upper confidence limits appearing in the Appendix C tables are artificially high. When used elsewhere in the SWEIS, such as in the analyses of human health impacts, these values thus (intentionally) result in conservative estimates of the consequences of LANL operations.

Data from Tables C–1 through C–7 were used in the study of the ingestion pathway in the human health analysis (section D.3.3 of appendix D). Data from Tables C–8 and C–9 are not used in the SWEIS but provided for additional information.

[a] (T) signifies that the total amount of the analyte in the sample was measured, that is, both the dissolved amount and the amount adsorbed to suspended particles.
[b] mg/l is milligrams of analyte per liter of sample; pCi/l is picocuries of radioactive analyte per liter of sample.
[c] Upper confidence limit (UCL) not calculated for number of detected analyses less than two.

[a] On-site, perimeter, and regional locations are in accordance with the Environmental Surveillance Program.
[b] pCi/l is picocuries of radioactive analyte per liter of sample, nCi/l is nanocuries of radioactive analyte per liter of sample, µg/l is micrograms of analyte per liter of sample, mg/l is milligrams of analyte per liter of sample.
[c] Upper confidence limit (UCL) not calculated when the number of detected analyses equals 1.

[a] Watershed includes both on-site and perimeter analyses as designated by the Environmental Surveillance Program.
[b] pCi/l is picocuries of radioactive analyte per liter of sample, nCi/l is nanocuries of radioactive analyte per liter of sample, µg/l is micrograms of analyte per liter of sample, mg/l is milligrams of analyte per liter of sample.
[c] Upper confidence limit (UCL) not calculated when the number of detected analyses equals 1.

[a] On-site, perimeter, and regional locations are in accordance with the Environmental Surveillance Program.
[b] pCi/g is picocuries of radioactive analyte per gram of sample, nCi/l is nanocuries of radioactive analyte per liter of sample, µg/kg is micrograms of analyte per kilogram of sample, mg/kg is milligrams of analyte per kilogram of sample.
[c] Upper confidence limit (UCL) not calculated when the number of detected analyses equals 1.
[d] Tritium is reported as nanocuries of tritium per liter of water because tritium in sediments exists as tritiated water. The water is distilled, and the tritium content of the water is measured.

[a] Watershed includes both on-site and perimeter analyses as designated by the Environmental Surveillance Program.
[b] pCi/g is picocuries of radioactive analyte per gram of sample, nCi/l is nanocuries of radioactive analyte per liter of sample, µg/kg is micrograms of analyte per kilogram of sample, mg/kg is milligrams of analyte per kilogram of sample.
[c] Upper confidence limit (UCL) not calculated when the number of detected analyses equals 1.
[d] Tritium is reported as nanocuries of tritium per liter (nCi/l) of water because tritium in sediments exists as tritiated water. The water is distilled, and the tritium content of the water is measured.

[a] Groundwater regime designations are in accordance with the Environmental Surveillance Program.

[b] pCi/l is picocuries of radioactive analyte per liter of sample, nCi/l is nanocuries of radioactive analyte per liter, µg/l is micrograms of analyte per liter of sample, mg/l is milligrams of analyte per liter of sample, NTU is nephelometric turbidity units.

c Upper confidence limit (UCL) not calculated when the number of detected analyses equals 1.

[a] Groundwater regime designations are in accordance with the Environmental Surveillance Program.
[b] pCi/l is picocuries of radioactive analyte per liter of sample, nCi/l is nanocuries of radioactive analyte per liter, µg/l is micrograms of analyte per liter of sample, mg/l is milligrams of analyte per liter of sample, NTU is nephelometric turbidity units.
[c] Upper confidence limit (UCL) not calculated when the number of detected analyses equals 1.

Note: Watersheds are defined in ER Project FIMAD map G105700, July 24, 1997.

Note: The analytical data provided in these tables were obtained from the Facility for Information Management, Analysis, and Display (FIMAD) in August, 1998. The data represent analytical results for surface soil samples collected by the ER Project with a begin depth equal to 0 inches and an end depth less than or equal to 12 inches. The data were obtained from ER Project-approved fixed-site analytical laboratories using standard analytical methods (EPA methods for organics and inorganics; LANL-approved methods for radionuclides). Field measurements, non-standard measurements (e.g. x-ray fluorescence), and measurements for non-chemical specific data (e.g. gross radioactivity) were excluded. Quality assurance/quality control data were also excluded. The ER Project may have removed contaminated soil in voluntary corrective actions subsequent to sampling; therefore, some analytical results may represent contaminants that have been removed since the samples were taken.

Note: Watersheds are defined in ER Project FIMAD map G105700, July 24, 1997.

Note: The analytical data provided in these tables were obtained from the Facility for Information Management, Analysis, and Display (FIMAD) in August, 1998. The data represent analytical results for surface soil samples collected by the ER Project with a begin depth equal to 0 inches and an end depth less than or equal to 12 inches. The data were obtained from ER Project-approved fixed-site analytical laboratories using standard analytical methods (EPA methods for organics and inorganics; LANL-approved methods for radionuclides). Field measurements, non-standard measurements (e.g. x-ray fluorescence), and measurements for non-chemical specific data (e.g. gross radioactivity) were excluded. Quality assurance/quality control data were also excluded. The ER Project may have removed contaminated soil in voluntary corrective actions subsequent to sampling; therefore, some analytical results may represent contaminants that have been removed since the samples were taken.

APPENDIX D
HUMAN HEALTH

D.1 PUBLIC HEALTH CONSEQUENCES: PRIMER AND RECENT STUDIES NEAR LANL

In this appendix, supplemental information is presented on the effects on human health of radioactive and chemical exposures. The information is presented in two sections: that addressing our general knowledge and understanding (section D.1.1) and that presenting in more detail the findings of the recent studies of public health in the community of Los Alamos, and New Mexico and U.S. studies (including Native Americans in New Mexico, Hispanic white and nonhispanic white populations throughout the U.S. (section D.1.2). The presentation in section D.1.1 is useful to the reader as a primer on human health effects of exposures to radioactivity or to chemicals. The summaries presented in section D.1.2 are the results of descriptive epidemiology studies. That is, they are analyses of disease incidence rates and causes of death using statistical analytical methodologies.

Exposure to toxic chemicals is regulated by other agencies, and DOE subscribes to and applies those regulations without change to its own activities. The Occupational Safety and Health Administration (OSHA) promulgates and enforces regulations for the protection of workers, and EPA regulates exposures to the public. Chapter 7 provides a detailed review of the regulatory requirements for the operation of LANL.

D.1.1 Primer on Human Health Consequences of Radiological and Chemical Exposures

Table D.1.1–1 summarizes the differences in consequences between exposures to radioactive materials and exposures to chemicals. More detailed information on the modes of exposure and potential effects of these exposures are given in the sections below.

D.1.1.1 *About Radiation and Radioactivity*

In the simplest sense, radiation is defined as energy propagated through space (NBS 1952). This definition covers a broad range, including visible light, radio and television transmissions, microwaves, and emissions from atomic and nuclear reactions and interactions. The method by which radiation interacts with matter is by transferring its energy to the atoms of the matter. The amount of energy transferred determines the effect that it will have on matter. The broad spectrum of radiation can be subdivided into two groups, ionizing and nonionizing. Ionization occurs when the radiation transfers enough energy to strip one or more electrons from the interacting atom. When ionization takes place in the body, it can cause chemical and physical changes that are of concern to human health. Radiation that does not have enough energy to strip electrons is called “nonionizing” (discussed further in appendix D, section D.2.2.2).

Ionizing radiation is used in a variety of ways, many of which are familiar to us in our everyday lives. The machines used by doctors to diagnose and treat medical patients typically use x-rays, which is one form of ionizing radiation. The process by which a television displays a picture is by ionizing coatings on the inside of the screen with electrons. Most home smoke detectors use a small source of ionizing radiation to detect smoke particles in the room’s air.

TABLE D.1.1–1.—*Comparison of Consequences of Radioactivity and Toxic Chemicals*

	RADIOACTIVE MATERIALS	TOXIC CHEMICALS
Threshold for effects?	Assume no threshold (stochastic effects).	Yes, and different thresholds for different effects.
Accumulative effects?	Assumed exposures accumulate over a lifetime, with no repair.	Typically, the body repairs itself between exposures; may build sensitive allergic reaction or interact with cells.
Sensory perception?	We do not feel, smell, or otherwise sense ionizing radiation.	Very low concentrations not sensed. Often an annoying odor and irritating effects at low concentrations. Some gases are visible when in high concentrations.
Carcinogenic?	All ionizing radiation is regulated as carcinogenic.	Only some chemicals are confirmed human carcinogens. Some others are suspected, and some are animal (mammal, or closer to human, primate) carcinogens.
Effects-exposure relationship?	Usually treated as linear at low doses, although this is a conservative simplification (BEIR V 1990).	Typically nonlinear and nonadditive. Thresholds exist. For some chemicals, effects can be treated as linear with exposures, but only over small ranges. Synergisms among chemicals are not understood.
Acute effects?	Acute deterministic effects are soon observed, but occur only above a threshold of about 50 rem (less for the eye).	Effects may be immediately observed for levels of exposures above the thresholds.
Entry paths of particulates into the body?	Radionuclides enter through inhalation, ingestion, and wounds. A few are absorbed through the skin.	Same routes, except a greater percentage of chemicals than of radionuclides are absorbed through the skin.
Target organs?	The chemistry of the radionuclide determines its residence time and location in the body.	Same as for radionuclides. Except, the body also metabolizes chemicals, sometimes into more toxic chemicals.
Penetrating?	Alpha and beta radiation do not penetrate skin. In contrast, dense materials are needed to shield against gamma and x-ray radiation.	About 20% of OSHA-regulated chemicals have skin as an import route of entry. Only corrosive chemicals penetrate protective gear rapidly.

Ionizing radiation is generated through many mechanisms. The two most common mechanisms are the electrical acceleration of atomic particles such as electrons, as in x-ray machines, and the emission of energy from nuclear reactions in atoms. This second process is termed "radioactive decay." Atoms are made up of various combinations of particles called protons, neutrons, and electrons. In most cases, the numbers of neutrons and protons are balanced such that the atom will stay together forever. An atom formed with too many of either the neutrons or protons will attempt to change itself into a more stable form. To do this, the atom will emit an atomic particle, such as an electron, normally called a beta particle, or a "packet" of energy called a photon. This is the process of radioactive decay. The time that it takes for the atom to decay is characterized by a value called the half-life. This is the time it takes for a quantity of radioactive material to decay to one-half its original amount. In general, radioactive materials are identified by their half-lives and the type and energy of their emissions. In some cases, atoms may emit a highly energetic, ionized, helium atom, called an alpha particle. The energy carried away by these emissions is normally capable of creating a large number of ionizations in matter.

Besides ionization, other particles can often be emitted during interactions between radiation and matter, depending upon the type and energy of the interaction. Neutrons, protons, and some other more exotic particles are often emitted during various processes. Nuclear reactors use neutrons to break apart, or fission, particular isotopes of uranium and plutonium in order to release heat and more neutrons to continue the reaction. Large machines, often called "atom smashers," cause atoms at high energies to collide and break apart, releasing particles in order to study their nuclear structure. However, due to the design and operation of these types of facilities, it would be highly unlikely for these types of radiations to reach the public outside the boundaries of the facility.

When an individual is in the presence of an unshielded radiation source, this is referred to as being exposed. The amount of ionizing radiation that the individual receives during the exposure is referred to as dose. The measurement of radiation dose is called radiation dosimetry, and is done by a variety of methods depending upon the characteristics of the incident radiation. The units of measure for radiation doses are normally rads and rem. (Note that the term millirem [mrem] is also used often. A millirem is one one-thousandth of a rem.) The rad is a measure of the energy deposited in the body by the radiation, regardless of the type of emission. The rem is a measure of the biological effect, by including the effectiveness of the particular type and energy of the incident radiation for causing biological effects. This is due to the fact that some heavier or higher energy radiations, such as alpha particles or neutrons, can deposit their energy into much smaller volumes, and consequently, cause more intense damage through localized, chemical changes.

When an individual is exposed to an unshielded radiation source, this is called external radiation. If radioactive material is incorporated into the body and consequently decays, it is called internal radiation. The external radiation is measured as a value called the deep dose equivalent (DDE). Internal radiation is measured in terms of the committed effective dose equivalent (CEDE). More information about the CEDE is presented in the discussion about the processes by which radioactive material enters the body. The sum of the two contributions (DDE and CEDE) provides the total dose to the individual, called the total effective dose equivalent (TEDE). Often the radiation dose to a selected group or population is of interest, and is referred to as the collective dose equivalent, with the measurement units of person-rem.

D.1.1.2 *About Radiation and the Human Body*

Ionizing radiation affects the body through two basic mechanisms. The ionization of atoms can generate chemical changes in body fluids and cellular material. Also, in some cases the amount of energy transferred can be sufficient to actually knock an atom out of its chemical bonds, again resulting in chemical changes. These chemical changes can lead to alteration or disruption of the normal function of the affected area. At low levels of exposure, such as the levels experienced in occupational or environmental settings, these chemical changes are very small and ineffective. The body has a wide variety of mechanisms that repair the damage induced. However, occasionally, these changes can cause irreparable damage that could ultimately lead to initiation of a cancer, or changes to genetic material that could be passed to the next generation. The probability for the occurrence of health effects of this nature depends upon the type and amount of radiation received, and the sensitivity of the part of the body receiving the dose.

At much higher levels of exposure, at least 10 to 20 times higher than the legal limits for occupational exposures, the body is unable to recover from the large amount of chemical changes occurring during the exposure. At these levels, damage is much more immediate, direct, and observable. Health effects range from reversible changes in the blood to vomiting, loss of hair, temporary or permanent sterility, and other changes leading ultimately to death at exposures above about 100 times the regulatory limits. In these cases, the severity of the health effect is dependent upon the amount and type of radiation received. Exposures to radiation at these levels are quite rare, and, outside of intentional medical procedures for cancer therapy, are always due to accidental circumstances.

For low levels of radiation exposure, the probabilities for induction of various cancers or genetic effects have been extensively studied by both national and international expert groups. The problem is that the potential for health effects at low levels is extremely difficult to determine without extremely large, well-characterized exposed populations. Therefore, only particular groups with fairly high exposures, such as atomic bomb survivors, radiation accident victims, and some groups receiving large medical exposures, can be studied to evaluate the probabilities. Unfortunately, the levels and rates of exposures, and the conditions under which they occurred, are very different from those in which the normal population is exposed to background radiation or to normal operational releases from nuclear operations. Therefore, expert groups must make significant approximations and assumptions in order to apply the study results to the lower levels of exposure. This is done in a manner that attempts to ensure that the resulting risk factors are conservative estimates of the actual probabilities. In other words, it is unlikely that the actual risks are greater than the estimates, while it is fairly likely that the actual risk is smaller than the estimate.

There is another type of study, referred to as an epidemiology study, that attempts to estimate the risk factors in populations with much lower doses than mentioned above. These studies are even more difficult to perform. There are two types of epidemiology studies: descriptive (based on statistical analyses of death and disease incidences) and analytical (case studies and observational analysis within a community or work force). The studies summarized in chapter 4, section 4.6.1.2, and appendix D, section D.1.2, are descriptive. The risk factors for radiation-induced cancer at low levels of exposure are very small, and it is extremely important to account for the many nonradiation related mechanisms for cancer induction, such as smoking, diet, lifestyle, and chemical exposures. These multiple factors also make it difficult to establish cause-and-effect relationships that could attribute high or low cancer rates to specific initiators. As a consequence, the results of such studies have not been generally accepted within the scientific community and are not currently used as the primary basis for establishing the risk factors.

Risk factors are estimated for a large number of fatal and nonfatal cancers, for hereditary effects, and a few other identified radiation-induced health effects. Table D.1.1.2–1 lists the fatal cancer risk factors used in this SWEIS, which are based upon the recommendations of a recognized authoritative international expert group, the International Commission on Radiological Protection (ICRP). The other, smaller risk factor in the table for nonfatal cancer and hereditary effects may be similarly applied by interested readers.

In keeping with the previous discussion of the difficulties in determining the risk factors used in this document, it is worthwhile to discuss the level of confidence that is associated with those factors. The ICRP, in the recommendation that established the risk factors used here, stated that, "The nominal values of fatal cancer risk, which form the basis of the detriment following radiation exposure, are not to be regarded as precise and immutable. They are, unfortunately, at this time still subject to many uncertainties and to many assumptions involving factors which may be subject to change. ...It is hoped, and indeed expected, that these uncertainties will diminish in the future as the accumulated experience in exposed populations such as the Japanese survivors increases and as more information develops from a broader variety of human experiences" (ICRP 1991). The Committee on the Biological Effects of Ionizing Radiations (BEIR), which developed the risk factors that the ICRP recommends, also discussed the uncertainty of the factors: "Finally, it must be recognized that derivation of risk estimates for low doses and dose rates through the use of any type of model involves assumptions that remain to be validated. ...Moreover, epidemiologic data cannot rigorously exclude the existence of a threshold in the millisievert (1 millisievert = 100 millirem) dose range. Thus the background radiation cannot be ruled out. At such low doses and dose rates, it must be acknowledged that the lower limit of the range of uncertainty in the risk estimates extends to zero" (BEIR V 1990).

Given these concerns, the reader should recognize that these risk factors are intended to provide a conservative estimate of the potential impacts to be used in the decision-making process, and are not necessarily an accurate representation of actual anticipated fatalities. In other words, one could expect that the stated

TABLE D.1.1.2–1.—*Risk Factors for Cancer Induction and Heritable Genetic Effects from Exposure to Ionizing Radiation*

EXPOSED POPULATION[a]	FATAL CANCER[b]	NONFATAL CANCER	HEREDITARY EFFECTS (SEVERE)[d]	TOTAL DETRIMENT
Adult Workers	0.0004[c]	0.00008	0.00008	0.00056
Whole Population	0.0005[c]	0.0001	0.00013	0.00073

[a] The distinction between the worker risk and the general public risk is attributable to the fact that sensitivities vary with age, general health, and other factors that contribute more to the general population than to the worker population.
[b] When applied to an individual, units are lifetime probability of excess cancer fatalities per rem of radiation dose. When applied to a population of individuals, units are excess numbers of fatal cancers per person-rem of radiation dose.
c This is the source of the 4 x 10^{-4} worker and 5 x 10^{-4} public risk factors used in this SWEIS.
[d] Heritable genetic effects as used here apply to populations, not individuals. For the other columns, the units would change accordingly, in terms of number of effects per unit dose.
Source: ICRP 1991

impacts from an activity or accident form an envelope around the situation, and that actual consequences could be less, but probably would not be worse.

When considering the risks from exposure to ionizing radiation, it is important to remember that we are always being exposed to the radiation in the environment around us. Natural background radiation is the collective term for all of the sources that occur naturally, such as cosmic radiation and naturally occurring radioactive materials, such as potassium, uranium, thorium, radium, and others. These sources contribute an average of 0.3 rem per year to each individual. Manufactured radiation sources contribute another 0.06 rem per year on the average, with the majority coming from medical procedures. Fallout from the atmospheric testing of nuclear weapons currently contributes less than 0.001 rem per year to our doses (NCRP 1987).

D.1.1.3 *About Radioactive Material Within the Body*

Typically, radioactive material that is released into the environment is in the form of very fine particulates, gases, or liquids. That is usually because these forms are the hardest to contain in a facility. This material is easily carried into and spread around the air, soil, and water. As these materials move through the environment, it is possible for them to be taken into the body, through breathing, eating, or drinking. During normal operations of a facility, every effort is made to minimize these releases to levels well below natural background. During accidents, it is possible that higher levels may be released; but, the facilities are designed and operated to control these releases as much as possible.

Radioactive material normally enters the body through one of three mechanisms. When the material is in the air, it is inhaled into the lungs, where a fraction will be trapped, depending upon the size of the particles. When it is ingested by eating or drinking, or by clearing of the respiratory tract, it passes through the stomach and into the gastrointestinal tract. Under the right conditions, it can also be absorbed through the skin or enter through open wounds.

Once in the body, the fate of the material is determined by its chemical behavior. Some material will be dissolved into bodily fluids and transferred into various organs of the body. Remaining material may either be retained at its point of entry, such as in the lungs, or pass through the body rapidly, as in the gastrointestinal tract. The effect of material in the body is characterized by the type of radiation it delivers and the organs in which it tends to collect. The rate at which the material is removed from the body is represented by a value called effective biological half-life (the time it takes for the activity in the body to be reduced to one-half as a consequence of radioactive decay and biological turnover of the radionuclide).

When radioactive material is in the body, it irradiates the living tissue around it. Some radiation types, like beta and alpha particles, are much more effective at causing changes when inside the body than when outside. This is because these types of radiation cannot effectively penetrate the dead layer of the skin from an external source. As mentioned above, the radiation dose from material inside the body is called the CEDE. Remember that the dose from an external source stops when you walk away or are shielded from it. But you cannot walk away from an internal source. Therefore, the CEDE is designed to determine the risk commitment from the intake. It is the dose that will be received over the next 50 years from the material in the body. Because of the assumptions that doses are cumulative and their effects are not repaired, this means that the lifetime risk from an internal source in rem CEDE can be directly compared to the risk from an external source in rem DDE.

D.1.1.4 *About the Material of Interest at LANL*

LANL has a large involvement in nuclear science and applications. Therefore, there are many types of radioactive material and radiation sources in use. However, many of the uses require only very small amounts of material. Note that all radioactive materials are considered in this SWEIS; but, there are three types that tend to dominate the human health effects and DOE accident scenarios. This is due to either their particular radioactive and biological characteristics, the quantities of material being used, or the potential for dispersion in an accident. These materials are plutonium, uranium, and tritium.

Plutonium is a man-made element that has several applications in weapons, nuclear reactors, and space exploration. There are several types of plutonium atoms, called isotopes, which are distinguished by the different numbers of neutrons in their nucleus. (Note that isotopes of a particular atom all behave the same chemically.) In most cases, the isotopes of plutonium of interest here decay by alpha particle emission with radioactive half-lives ranging from tens to thousands of years. There is nothing unique about plutonium as a health risk compared to other radioactive materials. It is only that once incorporated into the body, it tends to stay for a very long time and deposits a lot of localized energy due to its alpha particles.

Uranium is a naturally occurring radioactive element. The discovery that an atom of uranium could be fissioned with neutrons was the starting point of the Nuclear Age. Uranium-235 is one of several fissile materials that fission with the release of energy.

Various applications require the use of different isotopes of uranium. Because isotopes cannot be chemically separated, processes have been developed to enrich uranium to various isotopic ratios. Enriched uranium is uranium that is enhanced in the isotope uranium-235 above its natural ratio of 0.72 percent. Highly enriched uranium (HEU) is where the uranium-235 content is 20 percent or greater. Depleted uranium (DU) is where the content of uranium-235 is below its natural value. Obviously, natural uranium is where the material is in its natural isotopic ratios.

Most uranium isotopes of interest here have very long half-lives and are alpha emitters. Their half-lives are much longer than the plutonium isotopes, and as a result uranium is generally of lower radiological concern than plutonium. However, its actual radiological concern varies with its enrichment. As a heavy metal, uranium also can be chemically toxic to the kidneys. Depending upon the enrichment and chemical form, either chemical or radiological considerations will dominate.

Tritium is a radioactive isotope of hydrogen. It is generated at low levels in the environment by interactions of cosmic radiation with the upper atmosphere, but for practical applications it is normally produced in a nuclear reactor. Tritium has a half-life of around 12 years and decays by emitting a low energy beta particle. Because tritium is an isotope of hydrogen, it can be incorporated into the water molecule, forming tritiated water. In the environment, tritium is most often found either in its elementary form as a gas, or as water. Tritiated water is a significant concern to the human body because the body is composed mostly of water. This actually is a mixed blessing. Tritiated water will easily and rapidly enter the body and irradiate it rather uniformly; however, it also is removed from the body rather quickly, being easily displaced with regular water and with a biological half-life of about 12 days under normal conditions.

D.1.1.5 *How DOE Regulates Radiation and Radioactive Material*

Radiation doses to workers and the public and the release of radioactive materials are regulated by DOE for its contractor facilities. Under the conditions of the *Atomic Energy Act* (as amended by the *Price-Anderson Amendments Act of 1988)*, DOE is authorized to establish federal rules controlling radiological activities at DOE sites. The act also authorizes DOE to impose civil and criminal penalties for violations of these requirements. Some activities are also regulated through a DOE Directives System that uses contractual means to regulate the contractor activities.

Occupational radiation protection is regulated by the *Occupational Radiation Protection Rule*, Title 10 of the Code of Federal Regulations, Part 835 (10 CFR 835). Environmental radiation protection is currently regulated contractually with DOE Order 5400.5, which is in the process of being converted to a rule. There is a process by which these regulations are developed. The EPA, working with other agencies such as DOE and the NRC, develops a federal guidance document that is signed by the President (52 *Federal Register* [FR] 2822–2834). This document is based upon the recommendations of the National Council on Radiation Protection and Measurements (NCRP), and considers recommendations of international expert groups such as the ICRP. This federal guidance then becomes the basis for all federal regulations for radiation protection, including DOE's and also U.S. Nuclear Regulatory Commission (NRC) rules. This process ensures a common, scientifically based approach to all radiation protection in the U.S.

D.1.1.6 *About Chemicals and Human Health*

The characteristics and consequences of exposures to chemicals are quite different from those of exposure to ionizing radiation. Table D.1.1–1 summarizes the differences.

For noncarcinogens, there are threshold concentrations that must be exceeded for observable adverse effects to happen; whereas, for ionizing radiation it is assumed that the integrated (accumulated) exposure determines the likelihood of observable effects.

The threshold values for effects from toxic chemicals vary somewhat among individuals, but values can be determined that represent most of the more vulnerable people among the general population. The several different effects from a chemical each have different thresholds. For instance, there may be different concentrations that produce odor, irritation, effects that last only a short time, permanent effects, and death. Older and ill people, and those with a particular sensitivity such as respiratory problems, are more vulnerable and will have lower thresholds for effects.

Using human inhalation of chlorine in illustration, 0.2 to 0.4 parts per million (parts of chlorine per million parts of air) is the odor threshold; 1 to 3 parts per million for periods less than an hour produce burning eyes, scratchy or irritated throat, and headache; 15 parts per million is the lowest concentration observed to cause respiratory distress; no deaths were observed in any animals exposed to 50 parts per million for 30 minutes; and 210 parts per million has been estimated to be the 30-minute LC50 for humans, although 50 parts per million might cause death in some vulnerable individuals. (The 30-minute LC50 is defined as the concentration that produces 50 percent fatalities among individuals exposed for 30 minutes.)

The ability to resist a potential effect and to recover from that effect clearly depends upon a person's health and age. For the population of workers, presumed to have few individuals who are especially vulnerable, regulatory agencies set permissible exposure limits and average concentrations for the 8-hour and 10-hour work day. Lower values than these would be appropriate to public exposures; whereas, higher values are deemed acceptable for military personnel under military exigencies.

Again using inhalation of chlorine gas in illustration, the OSHA permissible exposure limit is a time-weighted average (TWA) over the 8-hour work day of 0.5 parts per million[1]. There also is an OSHA short-term exposure limit of a 1-part-per-million 15-minute TWA that should not be exceeded at any time during the work day. The immediately dangerous to life and health (IDLH) value is 30 parts per million; this is the concentration from which a worker could escape within 30 minutes without a respirator and without escape-impairing or irreversible effects.

This SWEIS analysis uses the TWA as a convenient measure for screening the chemical inventory at LANL, and then uses Emergency Response Planning Guidelines (ERPGs) or their surrogate Temporary Emergency Exposure Limits (TEELs) for bounding the consequences to persons exposed to a release to the atmosphere. ERPGs are provided by the American Industrial Hygiene Association (AIHA) for planning for emergencies, rather than for determining consequences. ERPG–1, ERPG–2, and ERPG–3 are defined and described in detail in appendix G, Accident Analysis. They are intended to provide protection for most members of the public, and so their exposure time (up to one hour) and their concentrations are directly related to effects (no safety factor of ten was applied).

1. The definition of the TWA is the sum of all the instantaneous air concentrations over the 8 hours, averaged by dividing by the 8 hours.

Again using chlorine in illustration, the ERPG–2 is 3 parts per million, the concentration at which nearly all individuals could be exposed without irreversible or other serious health effects or impairment of ability to take protective actions. The ERPG–3 is 20 parts per million, below which nearly all individuals could be exposed without life-threatening effects.

Only for some chemicals and only for a limited extent, effects are directly related to the product of the concentration and length of exposure ("Haber's Law"). Chlorine is not such a chemical. When attempting to apply an existing guideline to a different exposure period than for which the guideline applies, toxicologists must be consulted, and they will consider actual effects data.

D.1.1.7 *How Toxic Chemicals Affect the Body*

Some toxic chemicals can have direct effects upon the eyes and the skin through contact and can enter the body by absorption through the skin. These are considered in the derivation of guides and limits for airborne concentration. Toxic chemicals also can enter the body via ingestion (eating and drinking). All the LANL accidents considered in the SWEIS that pose significant risk to the public produce their exposure through airborne releases, and so airborne concentrations guides and limits are used in the screening and consequence analyses.

After intake, the chemical may follow primarily one or more routes within the body, involving the respiratory system and digestive system, the blood circulatory system, and the urinary tract. The route and residence time before excretion is strongly determined by the chemical's solubility, and if particulate, by its particle size. The chemical may be metabolized, usually in the liver, into other chemicals that are either more or less toxic. For carcinogens, the principal target organs (i.e., where the effects primarily occur) are the respiratory tract, urinary bladder, and to a lesser extent the bone marrow, gastrointestinal tract, and liver.

D.1.1.8 *About Chemical Carcinogens*

Some chemicals are regulated as carcinogens because they or their metabolites may cause cancer. There are limited data on chemical carcinogens for humans, and there are problems with applying the results of animal studies to humans. Therefore, these chemicals are classified as known human carcinogens, potential or suspected carcinogens, and chemicals that cause cancer in animals. Exposure to chemical carcinogens is treated in the same manner as cumulative exposure to ionizing radiation; that is, exposures are assumed to be additive in producing cancer.

Some chemicals are carcinogenic at concentrations that do not produce observable effects from acute (short-term) exposures. For these, the airborne exposure limits and guidelines are based on their carcinogenicity. Some chemicals may produce an irreversible change to cells (tumor initiation), which then may be submitted to chemicals that are promoters of cancer. Such promoters must be given repeatedly to be effective. For this reason, chemical carcinogens are regarded as additive to one another, and individual chemicals are regulated at 1/100 of the exposure level regarded as hazardous, perhaps to account for the conservative possibility of having 100 such chemicals in one's environment.

The carcinogenic effects of certain chemicals are similar to those of ionizing radiation and have been noted in virtually every organ, depending on the chemical, the species, and conditions of exposure. The cancers induced by chemicals and by ionizing radiation cannot be distinguished from cancers induced by other causes. Therefore, the effects of chemicals and ionizing radiation are inferred only on a statistical basis, and must inferred from exposures at higher doses and dose rates. The choice of model has a large influence on the estimated excess cancer risk. The extrapolation is made by assuming an uncertain and controversial no-threshold, linear mathematical relationship between dose and resultant effects. This model is usually thought likely to overestimate the risk at low doses, and so is often said to estimate the "upper limit" of risk (NCRP 1989).

Chemicals vary widely in their capacity to induce cancer. There are even fewer data on the carcinogenic effects for chemicals than for radiation. With most chemicals, assessment of risks for humans must be based on extrapolation from laboratory animals or other experimental systems. Hence, the risk assessment for chemicals has even more uncertainty than risk assessment for ionizing radiation (NCRP 1989). Ultimately, the desired certainty in risk assessment at low-level exposures to chemicals and radiation will require better understanding of their effects at all stages of carcinogenesis.

The EPA, in setting standards for compliance with the *Clean Air Act*, is required by judicial decision and the *Clean Air Act* to determine a "safe" level with an "ample margin of safety to protect public health" without consideration as to cost or technology feasibility (Bork 1987). After that level is determined, costs and feasibility can be considered in setting the standard. Although this decision applied specifically to vinyl chloride and the *Clean Air Act*, it aids in understanding the EPA challenge faced in determining what is "safe," "adequate," or "acceptable" when setting standards for protection of workers, public, and environment. In the attempt to provide an objective context for evaluating the risks posed by LANL operations, the SWEIS authors have searched for authoritative statement on acceptable risk levels. A few such statements and inferences can be found in ICRP, NCRP, EPA, and OSHA documents.

EPA regulations provide goals for environmental remediation (cleanup). The EPA goals "for acceptable exposure levels to known or suspected carcinogens are generally concentration levels that represent an excess upper bound lifetime cancer risk between 10^{-4} and 10^{-6}. The 10^{-6} risk level shall be used as the point of departure for determining remediation goals" when existing and relevant requirements are not available or sufficiently protective because there are multiple contaminants or pathways. When the combined risk from multiple contaminants exceed 10^{-4}, then factors such as detection limits and uncertainties may be considered in determining the cleanup level to be attained (40 CFR 300.430). Note that this is the lifetime risk to an undetermined public population group.

OSHA (OSHA 1997) expressed that its proposed worker permissible exposure limit for methylene chloride of 25 parts per million (average for 8 hours per day) would entail an employment lifetime risk of 3.62×10^{-3}, and that this was "clearly well above any plausible upper boundary of the significant risk range defined by the Supreme Court and used by OSHA in its prior rulemaking." OSHA noted that typical lifetime occupational risk for all manufacturing industries is 1.98×10^{-3}, and that the risk in occupations of relatively low risk, like retail trade, is 8.2×10^{-4}. Note that worker risk is generally accepted at a higher level than public dose because it is an accepted risk of employment. This is compatible with the EPA upper bound lifetime public cancer risk of between 10^{-4} and 10^{-6}.

D.1.1.9 *Radionuclides and Chemicals of Interest at LANL*

Radionuclides of interest at LANL are discussed with their respective emission facilities in appendix B, section B.1. Chemicals of interest are presented in appendix B, section B.2. LANL has used, uses, and will use a wide variety of chemicals because of its research mission. LANL has a chemical database that tracks the quantity and location of chemicals on site. About 51 of the chemicals tracked in the database are carcinogenic. A large number of the chemicals tracked in the database are toxic; that is, they are able to produce harm to humans. The analysis of the consequences to the public from chemical emissions under normal operations of LANL is provided in chapter 5, sections 5.2.4 and 5.2.6. Methodology is provided in section 5.1.4 and 5.1.6. Those of risk to the public, should they be accidentally released to the atmosphere, were determined by screening the entire database. Details on the accidental release screening and its results are presented in appendix G, Accident Analysis.

D.1.2 Supplemental Information on Public Health: U.S., New Mexico, and the Local LANL Community

The information presented below is supplemental to the information presented in chapter 4, section 4.6. It is presented to provide the context of the human health analysis provided in chapter 5, which estimates potential consequence to public health.

The population of Los Alamos County has grown primarily by immigration. The average annual fertility rate has remained at approximately 48/1,000 women across all races (DOC 1990 and Athas and Key 1993), which would produce annual growth of only 2.4 percent if there were no deaths. However, the growth rate has been approximately 25 percent between 1950 and 1960, more than 16 percent between 1960 and 1970 as well as between 1970 and 1980, and approximately 3 percent between 1980 and 1990.

Several studies have been conducted in the community due to concerns expressed within the community concerning the rates of some cancers. While these are summarized in section

4.6 of the SWEIS, additional information is presented here in order to meet the request of many during the scoping meetings for presentation of these results in the SWEIS.

These studies are largely descriptive; that is, they use statistical analyses to identify patterns of disease or death in a community. The thyroid cancer study (Athas 1996) reported below is a mixture of descriptive and analytical approaches (based on case studies and observational analyses). All epidemiological studies are subject to limitations in attempting to determine cause and effect relationships. Some of these limitations are:

- Small population sizes in the community to be studied
- Relatively few total numbers of cases of the specific disease or cancer to be studied
- High mobility in the population to be studied (if a large portion of the community has been in the community for shorter periods of time than that necessary to detect chronic disease, results are inconclusive)
- Disease etiology—one may have received the causative exposure decades before its diagnosis; households in the U.S. move on average every 3 years; in Los Alamos County in 1980, 45 percent of residents had been in the same home for 5 years; earlier census data showed lesser periods of time in the same residence
- Comparability—for instance, the makeup of Los Alamos County is quite dissimilar from its surrounding counties in ethnic distribution and in socioeconomic and occupational conditions
- Natural variability in disease incidence within the human population from any and all sources
- Increased technology efficiency used in disease detection, therefore, causing apparent increases in rates of incidence of the better-detected disease
- More than one causal agent suspected or known to cause the disease being studied, including lifestyle choices such as smoking and dietary patterns
- Disease cause from multiple sources in the same community
- Methodology limitations such as multiple comparison across differing time periods, across studies made for different purposes, consideration of all combinations across the study time frame, etc.

D.1.2.1 *Public Health: United States*

Heart disease remains the leading cause of death in the U.S. (Table D.1.2.1–1). There has been a significant decrease in mortality in the U.S. attributable to heart disease and cerebrovascular disease over the last 20 years. Cancer remains the second leading cause of death.

Table D.1.2.1–2 identifies the lifetime risk of dying from cancer for men and women by cancer type. Over all cancer types, the lifetime risk of dying from cancer is approximately 24 percent for men and 21 percent for women.

TABLE D.1.2.1–1.—*Leading Causes of Death in U.S.: Percent of All Causes of Death (1973 Versus 1993)*

CAUSE OF DEATH	PERCENT OF ALL CAUSES (1973)	PERCENT OF ALL CAUSES (1993)
Heart Disease	38.4	32.8

[a] SEER is the NIH/NCI Surveillance, Epidemiology, and End Results Program.
Source: Ries et al. 1996

Cancer incidence and mortality trends have changed over the last 20 years (Table D.1.2.1–3). Melanoma of the skin, for example, has increased in both incidence and mortality rate, as has brain and other nervous system cancers. Leukemia incidence and mortality rates have decreased.

D.1.2.2 *Comparison of Cancer Mortalities Between the U.S. and New Mexico*

A comparison of cancer mortality rates between the U.S. as a whole and New Mexico is given in Table D.1.2.2–1. These comparisons were made for 1989 through 1993 based on the National Institute of Health/National Cancer Institute (NIH/NCI) Surveillance, Epidemiology, and End Results (SEER) Program (Ries et al. 1996). For most cancers, differences were insignificant.

However, New Mexico had significantly higher mortality from thyroid cancer. (The reader is referred also to Athas 1996 for the local Los Alamos County study of thyroid cancer presented below.) New Mexico deaths due to thyroid cancers ranked 4th among the states. Thyroid cancers are associated with some types of radiological processes and research applications, principally those that could result in emitted radio-iodine. LANL has historically not used more than research amounts of radio-iodine. Radio-iodine emissions from LANL have been measured and have continually been very low (chapter 4, section 4.4 and the tables of emissions estimated for key LANL facilities, in chapter 3, section 3.6 discuss this further).

New Mexico had statistically lower rates of cancer mortalities for several cancers (Table D.1.2.2–1) relevant to the Los Alamos cancer studies, specifically, brain and other nervous system cancers and breast cancer.

D.1.2.3 *Cancer Incidence and Mortality Among Ethnic Groups Relevant to the LANL Area*

While the Native American population within Los Alamos County remains less than 3 percent (DOC 1990), the populations down gradient (with respect to air emissions and water flow) in the adjacent Santa Fe County Area are dominantly Native American (San Ildefonso Pueblo).

Table D.1.2.3–1 summarizes the findings regarding the top five cancers (both incidence and mortality) among nonhispanic whites (U.S.), Hispanic whites (U.S.), and Native Americans (New Mexico). The Native American cancer incidence and cancer mortality rates are lower than either of the other examined populations for both men and women. This is the case for all cancer types, not just the top five cancers with respect to incidence and mortality rate.

Among men, lung and prostate cancer dominate incidence and mortality. Among women, breast and lung cancer dominate cancer incidence and mortality. A fairly rare cancer, gall bladder, is the leading cause of cancer mortality among New Mexican Native American women. However, because there were so few cases, and the uncertainty level thus associated with the observation is so high, it is inappropriate to draw conclusions even regarding gall bladder cancer incidence in this population of women.

D.1.2.4 *Supplemental Information on Recent Studies of Los Alamos County Cancer*

Objectives

The primary objective of the study was to review Los Alamos County incidence rates for brain and nervous system cancer and other major cancers during the 21-year time period 1970 to 1990 (Athas and Key 1993). Secondary objectives were to review mortality rate data for select cancers of concern and to review Los Alamos County mortality data relating to benign brain and nervous system tumors.

Specific aims developed for incidence study were as follows:

- To calculate age-adjusted cancer incidence rates for Los Alamos County and a New Mexico state reference population using data of the New Mexico Tumor Registry (NMTR)
- To compare Los Alamos County cancer incidence rates to (1) incidence rates calculated for a New Mexico state reference population, and (2) national rates obtained from the SEER Program of the National Cancer Institute
- To determine if any of the Los Alamos County cancer incidence rates were elevated in comparison to rates observed in the reference population

The study protocol specified that statistical tests would be used to determine whether any of the Los Alamos County rates were elevated in comparison to the reference populations. Early in the course of the study, however, it became apparent that the small number of cases for virtually all of the Los Alamos County cancers reviewed would make the finding of statistical significance unlikely for small to modest elevations in a rate. Consequently, the analysis of the Los Alamos County incidence data was expanded to include not only statistical considerations but other types of information such as temporal patterns of cancer occurrence, prevalence of established risk factors, case characteristics, and tumor cell types. Cancers of concern were: oral cavity and pharynx, digestive system, respiratory system, melanoma of the skin, female breast, female genital system, urinary system, male genital system, lymphoreticular system, childhood cancers

TABLE D.1.2.3–1.—*The Five Most Frequently Diagnosed Cancer and the Five Most Common Types of Cancer Death (1988 Through 1992) Among White Non-Hispanics (all U.S.), White Hispanics (all U.S.), Native Americans (New Mexico)*

[a] NIH/NCI SEER Program statistics from several regions around the U.S.
[b] Statistics calculated with extremely high uncertainty because they are based on fewer than 25 cases. Other rates (not footnoted) were calculated from larger total numbers of cases and, therefore, have less uncertainty associated with them.
Source: Miller et al. 1996

(ages 0 to 19 years) thyroid, and brain and nervous system cancers.

Following a review of tabulated incidence rate data for 23 major cancers, nine were selected for additional review and evaluation: liver and intrahepatic bile duct cancer, non-Hodgkin's lymphoma, leukemia, melanoma of skin, ovarian cancer, breast cancer, childhood cancers, thyroid cancer, and brain and nervous system cancer. The majority of these cancers were chosen on the basis of incidence rates, which were higher in Los Alamos County in comparison to the reference populations. Childhood cancer was chose for further review based on mortality rate data showing an apparent excess of childhood cancer deaths in Los Alamos County. Leukemia and liver cancer where chosen as cancers of concern specifically to examine tumor cell types. Cancers not chosen for further review included major sites in the respiratory, digestive, and urinary systems.

Incidence Data: Data Sources

Information regarding newly diagnosed cancers among Los Alamos County residents and New Mexico non-Hispanic Whites was compiled from records collected since 1969 by the NMTR at the University of New Mexico Cancer Center. Cancer is a reportable disease in New Mexico by regulation of the New Mexico Department of Health (NMDOH). Since the late 1960's, NMTR has been the repository of the confidential medical record abstracts and computerized masterfile for cancer in New Mexico. NMTR has been a part of the SEER Program since that program began in 1973.

Cancer Incidence Findings (1970 to 1990)

All Cancers. Figure D.1.2.4–1 shows that the Los Alamos County incidence rates for "all cancers" fluctuated considerably; but the rates generally were comparable to or lower than rates observed in the state and national reference populations.

Liver and Intra-Hepatic Duct Cancer. Seven cases of primary liver and intra-hepatic bile duct cancer occurred in Los Alamos County. Four of the seven cases (57 percent) were diagnosed between 1981 and 1982. Los Alamos County incidence rates were highly variable as a result of the small number of cases and the clustered temporal distribution of cases. No cases were reported up until the early 1980's, at which time the four cases diagnosed in 1981 to 1982 caused a marked elevation in the Los Alamos County rates in comparison to the state and national reference rates (Figure D.1.2.4–2). Los Alamos County rates subsequently diminished to a level consistent with the reference rates.

Non-Hodgkin's Lymphoma. Los Alamos County consistently experienced a small to modest elevation in incidence compared to the reference populations (Figure D.1.2.4–3). The magnitude of the elevated Los Alamos County incidence varied widely up to a two-fold higher than expected level. None of the Los Alamos County lower confidence limits excluded the reference rates. Incidence in the Los Alamos County non-Hispanic White population was consistently higher than that observed in the total county population. All Los Alamos County rates were based on 14 or fewer cases. For the most recent five-year time period (1986 to 1990), the rate for non-Hispanic Whites in Los Alamos County was 57 percent greater than the state reference rate.

Leukemia. The incidence of leukemia in Los Alamos County generally was the same or lower than that observed in the reference populations (Figure D.1.2.4.–4). Wide fluctuations in the Los Alamos County rates occurred as a result of low case numbers. All Los Alamos County rates were based on nine or fewer cases. For the most recent 5-year time period (1986 to 1990), the Los Alamos County rate equalled the state reference rate.

Melanoma. The incidence of melanoma consistently was around 50 percent higher in New Mexico non-Hispanic Whites compared

FIGURE D.1.2.4–4.—*5-Year Average Annual Incidence of Leukemia, Los Alamos County, New Mexico NHW, SEER Whites, 1970 to 1990.*

with SEER Whites. Melanoma incidence steadily increased in both reference populations. Incidence rates in Los Alamos County were higher than the state reference rates over most of the 21-year study time period (Figure D.1.2.4–5). Early time periods were characterized by a small elevation in the Los Alamos County incidence; whereas, a more pronounced excess of melanoma in Los Alamos County began to appear in the mid 1980's. Beginning with the 1982 to 1986 period, and for all subsequent periods, the lower confidence limit of the Los Alamos County rate excluded the state reference rates. During these later periods, the incidence of melanoma in Los Alamos County increased roughly two-fold over that observed statewide.

Ovarian. Los Alamos County rates steadily rose by three-fold during 1970 to 1990, while both the sate and national reference rates remained essentially constant (Figure D.1.2.4–6). Initially lower than the reference rates, Los Alamos County incidence climbed to a statistically significant three-fold excess level during the 1982 to 1986 period. Half of all the Los Alamos County cases (15 out of 30) were diagnosed during these 5 years. Los Alamos County ovarian cancer incidence was two-fold higher than that observed in the state during the most recent 5-year period (1986 to 1990).

Breast. Breast cancer incidence in Los Alamos County women varied little over time; whereas, both reference populations displayed increasing incidence over time (Figure D.1.2.4–7). Los Alamos County incidence rates were 10 percent to 50 percent higher than the state and national reference rates over the entire study period. The lower confidence limits for the Los Alamos County rates consistently were near the reference rates, but excluded the reference rates in only several instances.

Childhood Cancers. Los Alamos County childhood cancer rates fluctuated around the more stable state and national reference population rates (Figure D.1.2.4–8). Following an initial two-fold elevation during the earliest

[a] Incidence rate data based on independent time periods and not 5-year moving averages.

period (1970 to 1972), subsequent periods were characterized by incidence rates that were slightly higher than or lower than the reference incidence rates. Two childhood brain cancer cases not in the original childhood cancer data set were discovered through a supplemental review of childhood cancer mortality statistics. The two additional cases, diagnosed in 1978 and 1980, would raise the original 1978 to 1982 Los Alamos County rate (13.7 per 100,000) by about 50 percent to 20.3 cases per 100,000. For the latest period (1988 to 1990), the incidence of childhood cancers in Los Alamos County was roughly 50 percent lower than that seen in the state reference population; however, the Los Alamos County rate was based on only one case.

Thyroid. The incidence of thyroid cancer in Los Alamos County prior to the mid 1980's was roughly stationary and less than two-fold higher than that seen in the reference populations (Figure D.1.2.4–9). Los Alamos County incidence rates began to rise during the mid 1980's and continued to climb up until the latest time interval (1986 to 1990). The incidence of thyroid cancer in Los Alamos County during 1986 to 1990 was nearly four- fold higher than that observed in the state reference population. The near four-fold elevation for Los Alamos County was statically significant. Roughly half (17 out of 37) of all thyroid cancer cases that occurred in Los Alamos County between 1970 and 1990 were diagnosed during the 1986 to 1990 interval.

Brain and Nervous System. The incidence of brain cancer in Los Alamos County increased over time (Figure D.1.2.4–10). Los Alamos County incidence rates were lower than or comparable to the reference rates up until the mid 1980's. Increases in Los Alamos County brain cancer incidence became apparent during the mid to late 1980's. Los Alamos County incidence rates (all races) during this period were 60 to 80 percent higher than rates for the state and national reference populations. Diagnosed in 1978 and 1980, two additional

cases raised the central portion of the incidence rate curve to a range more comparable with the reference rates, but had no effect on the rates observed during the period of elevated incidence.

Mortality

Mortality rates for Los Alamos County and the U.S. were obtained as age-adjusted average annual mortality rates from the National Center for Health Statistics (NCHS) and the National Cancer Institute. All rates were standardized to the 1970 U.S. standard population and were race-specific for Whites. Site-specific Los Alamos County mortality rates were available for the periods 1969 to 1972, 1973 to 1977, 1978 to 1982, and 1983 to 1987. U.S. rates were available for the time period 1968 to 1972. For some cancers, both Los Alamos County and U.S. rates were available for the period 1968 to 1972. The confidence intervals that accompany the mortality rates were calculated as described for the incidence rates. Table D.1.2.4–1 summarizes the mortality rates by cancer type for Los Alamos County. Nationwide rates are also reported for comparison.

Subcounty Cancer Incidence

Table D.1.2.4–2 describes the cancer incidence for the five census tracts within Los Alamos County for all races, 1980 to 1990. The New Mexico non-Hispanic White population rates are provided also.

D.2 METHODS USED FOR THE ESTIMATION OF HUMAN HEALTH CONSEQUENCES OF CONTINUED LANL OPERATIONS

The consequences of continued operations of LANL to public health and to LANL workers are evaluated in this SWEIS. The consequence analysis is based on several exposure scenarios that are conservatively defined in order to estimate potential maximum doses and risks (e.g., excess latent cancer fatality [LCF]) to the public and workers under normal operations in each of the four alternatives examined. (The consequences of credible and less than credible accidents on workers and the public are detailed in appendix G.)

D.2.1 Methods Used to Evaluate Public Health Consequences from Routine Operations

Public health consequences of continued LANL operations were based on several exposure scenarios, including exposure to external radiation, inhalation of airborne radioactivity and chemical emissions, ingestion of water and foodstuffs and inadvertent ingestion of sediments and soils, and dose received due to incident-free transportation to or from LANL. The methodology used to estimate dose to the public from external radiation and airborne radioactive and chemical emissions is given in appendix B. The methodology used to estimate dose from transportation to or from LANL is given in appendix F. The methods used to estimate dose, hazard, and cancer risk from radioactive and chemical intakes (inhalation and ingestion) are detailed below.

The estimation of potential dose and risk used in the public health consequence analysis was directed at estimating total risk. That is, the risks posed by all sources, including LANL, other anthropogenic sources, fallout and regional depositions such as through rainfall, and naturally occurring radionuclides and chemicals, were evaluated. For those radionuclides and chemicals shown to have risk probabilities greater than 1 in 1 million (1×10^{-6}) per year, the relative contribution of LANL operations versus other sources of risk was examined.

D.2.1.1 *Methods for Evaluation for External Radiation Risk and Inhalation Dose/Risk from Airborne Radionuclides and Chemicals*

The exposure pathways for members of the public were estimated for specific exposure scenarios and are "hypothetical" (that is, a person hypothesized to be present for a portion of the time or all the time that is conservatively located rather than by using actual location, such as assuming that a person is resident at the fenceline of a facility) members of the public. These include ingestion exposure scenarios for Los Alamos County residents, non-Los Alamos County residents, nonresident recreational users of canyons, resident recreational users of canyons, and people who could be exposed via special pathways. Special pathway exposures are through culturally associated lifestyle patterns such as increased use of herbal teas made from local vegetation, use of locally collected herbal smoking materials, working with clays, or increased consumption of local foodstuffs including game species resident/ migrating through the LANL reservation.

External Radiation and Airborne Radioactivity

For radioactive emissions from LANL facilities, population consequences were estimated to a radial distance of 50 miles (80 kilometers). Both point-source and diffuse source emissions were included in the analysis. Using the model CAP–88 (EPA 1992), the direct exposures (the sum of external radiation and inhalation and ingestion of airborne emissions) were estimated for each of the four alternatives for continued operations of LANL. The maximally exposed individual (MEI) was determined to be near the Los Alamos Neutron Science Center (LANSCE) (appendix B).

For individuals, the risk of excess LCFs was estimated for each alternative based on the recommendations of the International Commission on Radiological Protection (ICRP 1991), which provide the conversion of 0.0005 excess LCFs per rem of exposure (Table D.1.1.2–1).

Toxic Chemicals

Inhalation of airborne chemicals was evaluated on a TA-specific basis in the nonradiological air quality analysis presented in appendix B. The chemicals identified in this screening for public health consequence analysis were reviewed as described in section B.2.3.1.

First, a qualitative evaluation was made of the chemical's reference dose, toxicity, potential carcinogenicity, and chemical form(s) likely in the LANL area (both as released and upon deposition onto soils, waters, and sediments). Several chemicals identified in the very conservative nonradiological air screening process were eliminated from subsequent public health consequence analysis using these qualitative evaluations.

For the remaining chemicals, quantitative evaluation was made based on the modeled predicted concentrations at the nearest location where a member of the public could be exposed. The modeling methods are described in appendix B, as are the results for the modeled chemicals at specific TAs.

The factors used for quantitative analysis are those given in the *EPA Exposures Factors Handbook* (EPA 1997a). The exposure scenario assumed that a member of the public could be exposed to the average and 95th percentile concentrations of the chemical at that nearest location to the source. Average and worst-case (95th percentile) uptakes were calculated as milligram per kilogram-day for a standard adult human male.

Average and worst-case hazard indices were calculated (EPA 1997a): milligram per kilogram-day estimated per milligram per kilogram-day reference dose for the chemical. In some cases, no reference dose has been provided by EPA's IRIS (EPA 1997b). In instances where carcinogens or suspected carcinogens had no hazard index available, if unit risk factors were available, they were used to estimate potential risk to the MEI.

D.2.1.2 *Methods for Estimation of Ingestion Risks from Radionuclides and Chemicals*

Concentrations of radionuclides and chemicals in environmental media were used in dose/risk analysis. The data used were those from LANL's Environmental Surveillance Reports 1991 to 1996 (appendix C). The 95th percentile upper confidence level (95 percent UCL) values were used in order to provide a conservative analysis (calculated using only measurements above zero or the detection threshold).

Data from specific contaminated sites were used to provide insight to potential additional but short-term exposures that could contribute to dose/risk. These datasets are also provided in appendix C.

Table D.2.1.2–1 presents the specific exposure pathways evaluated for the five exposure scenarios: residents (both Los Alamos and non-Los Alamos County), recreational users (residents and nonresidents), and special pathways. These exposure scenarios are defined below.

TABLE D.2.1.2–1.—*Ingestion and Hypothetical Receptors Used to Evaluate Radiological Dose and Potential Public Health Consequence*

[a] Receptor is a hypothetical person who is conservatively estimated to have intake of the 95th upper confidence limit (UCL) concentration of a contaminant in the specific medium evaluated for ingestion.

[b] The resident recreational user lives in Los Alamos County or a neighboring county and is in the Los Alamos canyons 24 visits per year, approximately 8 hours per visit. The nonresident recreational user lives outside the region of influence of LANL but hikes into the canyons 12 visits per year, approximately 6 hours per visit.

[c] Special pathways receptors are those who have traditional Native American or Hispanic lifestyles.

[d] Elk muscle.

[e] Elk heart and liver.

ESD = Environmental Surveillance Data

NA = Not applicable

The doses/risks from ingestion pathways were examined as total ingestion risk, resulting from all contributors to the concentrations of radionuclides and chemicals in foodstuffs, water, and soils/sediments. The concentrations include naturally occurring radionuclides and chemicals, residual contamination from worldwide fallout and earlier LANL operations, and small quantities of contamination from more recent operations. Because it is difficult to differentiate among these sources for most materials, this SWEIS analysis calculates the total risk from all these sources. (If this analysis demonstrated elevated risks from a particular contributor, then it would be investigated to determine its possible sources.)

The exposures through ingestion were calculated using the 95 percent upper confidence limit (UCL) concentrations. In calculating the UCL, all samples of zero or negative value or less than the detection limit were rejected. This significantly increases the average value and the UCL, and especially so when a large fraction of the samples show no detectable contamination. Based on the projected emissions and effluents under the four alternatives (section 3.6), there are no incremental differences in dose/risk from operations continuing at LANL for the next 10 years. Therefore, the ingestion dose/risk analysis was provided only in the No Action Alternative.

The consumption rates used for estimating dose/risks at both 50^{th} and 95^{th} percentile were taken from the *EPA Exposure Factors Handbook* (EPA 1997a, except where only available in 1989 edition). In each dose/risk ingestion analysis provided, the specific data used were identified as well as the intake rates and any conversion factors. Because these differ among radionuclides and chemicals analyzed, they are only provided in the dose/risk analysis detailed tables (section D.3.3).

Off-Site Resident

Two different types of off-site resident were analyzed: one of these represents Los Alamos County residents; the other represents non-Los Alamos County residents and was located near the Otowi Bridge (outside Los Alamos County) in an agricultural area.

Los Alamos County Off-Site Resident. Because there is no meat or milk production from Los Alamos County, there are no viable meat or milk ingestion pathways for any doses to residents in Los Alamos County. The Los Alamos County resident was assumed to have a garden at his or her home, and it was conservatively assumed that a portion of the resident's produce (fruit and vegetables) was obtained from this garden. The resident in Los Alamos County would use water from the Los Alamos County water supply.

Thus, the pathways for the off-site resident in Los Alamos County would include ingestion of produce, fish, honey, game animals, pinyon nuts, groundwater, and inadvertent ingestion of sediments and soil. Doses for ingestion pathways were primarily determined using the concentrations in the various media measured in LANL environmental surveillance programs (LANL 1992, LANL 1993, LANL 1994, LANL 1995, LANL 1996a, and LANL 1996b). These consumption rates are provided in Table D.2.1.2–2.

Non-Los Alamos County Off-Site Resident. The exposure pathways that are applicable to this off-site resident are the same as those for the Los Alamos County off-site resident, with the following exceptions. Two additional pathways were evaluated for non-Los Alamos County residents: ingestion of meat and ingestion of milk from sources outside of Los Alamos County but within the LANL region of influence (based on current LANL surveillance data, 1991 to 1996).

TABLE D.2.1.2–2.—*Consumption Rates Used for Public Health Consequence Analysis*

INGESTION PATHWAY	INGESTION RATE PER YEAR	
	AVERAGE VALUE (50%)	WORST-CASE VALUE (95%)
Produce	202 kg	587 kg
Milk Products	210 liters	778 liters
Meat	55 kg	134 kg
Fish	7 kg	7 kg
Honey	1.4 kg	5.0 kg
Pinyon Nuts	1.5 kg	none given
Water	550 liters	891 liters (90th percentile)
Soil and Sediments	0.036 kg	0.146 kg
Homegrown Fraction: Vegetables[a]	25%	40%
Homegrown Fraction: Fruit[a]	20%	30%

[a] EPA 1989

Recreational Users

The nonresident recreational user was defined in this analysis as a person who occupies on-site canyons during 12 visits per year, for 6 hours per visit. The resident recreational user was hypothesized to be resident in Los Alamos or neighboring counties and to spend an average of 2 visits per month, 8 hours per visit, in the canyons as an avid local outdoor enthusiast.

Special Pathways

Special pathways were also evaluated to assess potential impacts to Native American, Hispanic, and other traditional lifestyle receptors that might not be bounded by the hypothetical MEIs of residents and recreational users. The following exposure pathways were evaluated:

- Ingestion of game animals from the LANL area
- Ingestion of fish from the Cochiti reservoir
- Ingestion of native vegetation through the use of herbal teas
- Dermal absorption of sediments during craft or ceremonial use of clays
- Inhalation of local herbaceous plant materials via smoking
- Ingestion of surface waters from LANL
- Ingestion of soils and sediments from LANL
- Ingestion of locally grown produce

After investigations via interviews, it was determined that potential dermal absorption of contaminants from use of native clays for pottery is not a viable pathway. Clays are taken from specific areas and at depths that are not subject to appreciable contamination. Also, it was determined that potential uptakes via bathing or ceremonial uses of springs is not a viable pathway at LANL because there are no known permanent springs of sufficient size for such use. Finally, smoking use of herbs was not evaluated as a pathway because these are used in concert with tobaccos and do not significantly differ in risk than the risk posed by commercial tobacco use.

D.2.2 Worker Health

The methods used to estimate potential consequences to the health of workers from continued operations of LANL are given below.

These methods address: ionizing and nonionizing radiation, chemical exposures, and physical safety hazards during normal operations in LANL. The methods and consequences of accidents are addressed in appendix G.

D.2.2.1 *Radiological Consequences to Workers*

The worker radiation dose projected for this SWEIS is the total effective dose equivalent incurred by workers as a result of routine operations. The dose is the sum of the external whole body dose as monitored by personnel dosimeters, including dose from both photons and neutrons, and internal dose, as required by 10 CFR 835. The internal dose is the 50-year CEDE. However, the internal dose being projected is that for tritium, and does not include dose from incidents with plutonium or other nuclides. The internal dose from inhalation of plutonium occurs almost entirely from a breakdown of control or equipment, and is not predictable. Past plutonium exposures, such as the examples described in chapter 4 of volume I (Table 4.6.2.1.–1), are reported to DOE and have been included in the 1993 to 1995 baseline. Note that in 1996, plutonium produced measurable dose in two workers, contributing 4.8 person-rem to the worker collective dose. These incidental exposures are small compared to the total collective dose, which runs about 200 person-rem.

The collective doses for each LANL group and contractor, as monitored by the LANL Radiation Protection Program, were collected for 1993, 1994, and 1995 (LANL 1995, LANL 1996a, and LANL 1996b). The collective doses for the 3 years were summed for each group, and the groups were ranked by their total collective doses. Because of a major LANL reorganization in 1993 and 1994, many groups that were operating in 1993 and 1994 disappeared in 1995. Their functions were typically assumed by another group. This did not affect the major groups receiving radiation doses at LANL, which are listed in Table D.2.2.1–1 except for some groups at LANSCE (then called the Los Alamos Meson Physics Facility [LAMPF]). For these exceptions, the old groups were tracked to their new LANSCE counterparts through interviews with LANSCE personnel.

The 12 groups with the greatest total collective doses from 1993 through 1995 comprised more than 80 percent of the total collective dose for all LANL workers during that period. In addition to these 12 groups, groups that contributed more than 1 percent of the total LANL collective dose during this timeframe were interviewed to determine whether they would become major contributors to the collective dose in the future.

This process resulted in the identification of 15 groups that combined to contribute more than 84 percent of the collective LANL worker dose from 1993 to 1995 (Table D.2.2.1–1). These groups are included in the detailed radiation dose projections and analyses under each of the four SWEIS alternatives, based on the alternative descriptions and on historical exposure information. The following data were obtained for each of these groups:

- The group collective dose under each SWEIS alternative
- The group total collective dose from all programs for each alternative
- The number of workers with nonzero doses for each of the alternatives, as defined by LANL (Workers with measurable doses are referred to as nonzero dose workers.)

In order to obtain the total number of workers with nonzero dose for the entire laboratory, the index data were used to calculate a ratio of the number of workers with nonzero doses to the total number of workers monitored for radiation doses for the entire laboratory. Approximately 51 percent of the workers receiving a nonzero dose belong to the 12 groups that received the

[a] Numbers may not total exactly due to rounding.
[b] These groups were combined in 1996.
[c] Refers to a group of workers and not to the entire key facility known as LANSCE.

largest dose from 1993 to 1995, and 49 percent belong to the rest of the laboratory.

Once the above group data were collected, the following steps were taken to determine the worker collective dose, the average nonzero worker dose, and the cancer risk associated with these doses:

- For each alternative, the dose projections for the groups listed in Table D.2.2.1–1 were totaled. The sum was then divided by 0.844 (the fraction of the total laboratory dose comprised by these groups from 1993 to 1995) to estimate the total collective dose for LANL.
- The total collective dose was then divided by the fraction of workers projected to have nonzero doses to obtain the average nonzero worker dose for the entire laboratory.
- A dose-to-risk conversion factor of 4×10^{-4} excess LCF per person-rem (Table D.1.1.2–1) was used to determine the risks associated with the above doses in Table D.2.2.1–2.

It should be noted that actual doses received by workers will vary to some degree based on the actual work assignments made at LANL. For example, the Particle Physics Studies group may again become involved in activities at LANSCE and may again incur some worker dose. Other groups may incur more or less dose than is projected using this methodology. The approach taken in this analysis is considered conservative (in particular, use of the 0.844 normalization factor changes the entire LANL

TABLE D.2.2.1–2.—*Worker Dose for Baseline and Alternatives*

ALTERNATIVE	COLLECTIVE DOSE (PERSON-REM/ YEAR)	COLLECTIVE EXCESS LCF RISK (LCF/YEAR)	AVERAGE DOSE (MILLIREM/ YEAR)	INDIVIDUAL EXCESS LCF RISK (LCF/YEAR)
Baseline (1993 to 1995)	208	0.083	0.097	3.9×10^{-5}
No Action	446	0.178	0.135	5.4×10^{-5}
Expanded Operations	833	0.333	0.235	9.4×10^{-5}
Reduced Operations	170	0.068	0.083	3.3×10^{-5}
Greener	472	0.189	0.141	5.6×10^{-5}

collective worker dose in a manner proportional to the changes incurred by the 15 groups with the greatest doses).

The collective and average measurable dose for the No Action Alternative are larger than those for the baseline. This is because the No Action Alternative includes projects that are not now being performed and that were not performed in 1993 to 1995. The average dose is expected to increase significantly in the Expanded Operations Alternative because the programs are expected to expand at a greater rate than is the number of radiation workers. As noted earlier, the dose projections include the doses from external radiation and tritium, but not from other radionuclides (such as plutonium). This is because past and present bioassay for radionuclides within the body are not sensitive to the low intakes typical of normal operations. A new method having significantly improved sensitivity for analyzing bioassay samples is now under development. This will not change the dominance of external radiation and tritium, however, but will permit a more accurate quantification of the internal doses from other radionuclides.

Despite the appearance in Table D.2.2.1–2 of the three significant digits that resulted from the process, the projected doses are, at best, only approximations. The parameters that affect the dose estimates have considerable variability, such as whether a program will be funded and at what level, what the final work practices will be, and mitigating factors such as shielding and controls that will be employed in implementing the as low as reasonably achievable (ALARA) process. Because of these uncertainties, an attempt was made to maximize the estimates given here by using the upper limit of the dose that could arise from a particular operation. This may have had an effect on the differences between the alternatives, but not likely upon their relative ranking as to worker dose. In any case, for all alternatives the average individual worker dose and the administrative control level for the individual are much lower than the standard of 5 rem per year.

DOE (10 CFR 835) requires that the ALARA process be applied to reduce worker exposure to ionizing radiation. The DOE also has set an administrative control level of 2 rem per year for an individual worker exposure, and LANL has set a level of 1 rem per year. These levels can be intentionally exceeded only with higher level management approvals.

Occasionally, however, individual radiation workers might be given permission to exceed this level if sufficient justification exists. It is not anticipated that any of the groups will request permission to exceed the DOE administrative control level (ACL) of 2 rem per year. Therefore, the maximum worker dose for any of the SWEIS alternatives was estimated to be approximately 1.95 rem per year for the purposes of this SWEIS. This maximum dose estimate would not vary across alternatives and would remain below 5 rem per year in the absence of accidental exposures.

D.2.2.2 *Nonionizing Radiation Consequences to Humans and Other Biota*

A review of the LANL OSHA 200 Logs (LANL 1990 to 1996) and of DOE's Occurrence Reporting and Processing System (ORPS) reports (LANL 1990 to 1995) was performed to identify any reported injuries to workers from nonionizing radiation. Because there are no incidences of nonionizing radiation injuries to workers, a hypothetical analysis of a worst-case exposure was hypothesized for the SWEIS.

In order to perform this analysis, a methodology was needed to relate a transmitter output to biological effect. The methodology developed was consistent with NCRP 67 (1981), NCRP 86 (1986) NCRP 119 (1993), Cember (1996), and Calder (1984). A spreadsheet was developed that allows the input of transmitter parameters (power, frequency, and antenna size), receptor parameters (exposure area, organism density, organism specific heat rate), and exposure parameters (distance and exposure time) to be used to determine the rise in receptor temperature due to an exposure. Additionally, the spreadsheet was used to determine the power densities at specific distances or the distance to a specific power density.

Four typical targets of interest were chosen for microwave radiation exposure at the TA–49 microwave transmitter: human, to represent both workers and the public at the nearest potential exposure point; zone-tailed hawk, to represent birds of all sizes in the Jemez Mountains; coyote, to represent middle-range animals; and elk, to represent large grazing animals. Exposure duration is governed by the operation of the microwave transmitter and is typically limited to short bursts. These give the range of potential effects of nonionizing radiation on higher order complex animals.

The area immediately around the transmitter(s) is secured. The closest that a member of the general public can get to a transmitter is approximately 1,640 feet (500 meters) to the southwest, along State Route 4. By procedure, all microwave experiments are directed east, away from State Route 4. Procedures do not permit directing the microwave beam above the horizontal plane. On site, the downrange microwave beam path is secured to a distance of 3,280 feet (1,000 meters). The receiving antenna(s) can be positioned anywhere along the beam path. Beyond 3,280 feet (1,000 meters), the beam path is uncontrolled other than by the remoteness of the facility.

The results are expressed as increased body temperature as a result of a short burst exposure. This estimate is conservative because even exposure to 1 second from the source is extremely unlikely. Results for potential microwave exposures for the targets of interest are given in Table D.2.2.2–1. Beyond the distances given in Table D.2.2.2–1, and more typical of the distances humans would be from the microwave source, body temperature increase would be less than that given in the table.

There is no increase in body temperature of humans or other animals evaluated for a 1-second exposure to microwaves. The negligible consequences resulting from body temperature rise of a target would not approach any critical metabolic temperature. However, body temperature changes could be greater if the person or animal were exposed for long periods, or were closer to the source, or if there were increased power output.

D.2.2.3 *Chemical Exposures Consequences to Workers*

There have been no fatal or disabling chemical exposures at LANL in the 1990's, and there is no reason to expect that this would change under any of the alternatives analyzed in this SWEIS.

TABLE D.2.2.2–1.—*Temperature Rise Due to Microwave Exposure (1-Second Exposure Duration)*

TARGET	DISTANCE IN FEET (METERS)	BODY TEMPERATURE RISE (°C)
Zone-Tailed Hawk	1,640 (500)	0.016
Coyote	3,280 (1,000)	0.0055
Elk	3,280 (1,000)	0.0036
Human	1,640 (500)	0.021
	3,280 (1,000)	0.0052

°C = degrees centigrade

It is anticipated that there would continue to be a few, less serious exposures annually, particularly exposures to: airborne asbestos, lead paint particulates, crystalline silica, fuming perchloric acid, hydrofluoric acid, or skin contact with acids or alkalis. These would be similar to those listed in Table 4.6.2.1–2.

Rates of such chemical exposures were projected by alternative on the basis of changes in the LANL worker population. During the recent years (1990 to 1996) reportable chemical exposures occurred at a rate of one to three incidents per year at LANL, and the worker population was approximately 9,000 individuals. Therefore, the current rate of injuries was used to estimate the number of injuries occurring during continuing operations of LANL, assuming the same rate is experienced in the projected workforce for each of the four alternatives. Although LANL has undertaken a chemical hygiene program that should reduce the rate of chemical exposures in the future, this methodology assumes no additional benefits from implementation of this program.

Beryllium

There is an ongoing beryllium worker monitoring program at LANL within the facility (Sigma) where beryllium is processed in quantities and chemical forms posing worker hazards.

The Chronic Beryllium Disease (CBD) Program Plan elements consist of conducting a baseline inventory and sampling, conducting hazard assessments, conducting exposure monitoring, reducing and minimizing exposures, conducting medical surveillance, providing training, keeping records, and providing performance feedback. Exposure reduction and minimization includes reducing airborne levels of beryllium as-low-as-practical, minimizing the number of current workers exposed and potentially increasing the number of early treatment options that may slow the progression of CBD and reduce health impacts and reduce mortality incidence. The disability associated with CBD is believed to be minimized by early detection of the disease. Workers sensitized to beryllium or with CBD are offered placement in positions without beryllium exposure to maintain employment, and are assured of secure benefits that provide medical care.

The presentation and progression of CBD are highly variable. A percentage of individuals with positive peripheral blood beryllium-induced lymphocyte proliferation test (Be-LPT) results go on to be diagnosed with CBD even though clinical signs and symptoms of CBD are not present at the time of the test.

The qualitative consequence analysis presented in chapter 5 was based on (1) engineering controls and the health and safety program to be implemented when the Beryllium Technology Center is opened in late 1998, and (2) industry standards and exposure limits under OSHA, as well as recommendations of American Conference of Governmental Industrial Hygienists (ACGIH) and National Institute for Occupational Safety and Health (NIOSH). These are summarized below.

OSHA Beryllium Exposure Limits

The OSHA General Industry Standard (20 CFR 1910.1000) establishes the following permissible exposure limits for beryllium:

- *8-Hour Time Weighted Average, 2 micrograms per cubic meter*—An employee's exposure to beryllium and its compounds in any 8-hour work shift of a 40-hour work week shall not exceed 2 micrograms per cubic meter.
- *Acceptable Ceiling Concentration, 5 micrograms per cubic meter*—An employee's exposure to beryllium and its compounds shall not exceed at any time during an 8-hour shift the 5 micrograms per cubic meter acceptable ceiling concentration limit.
- *Acceptable Maximum Peak Concentration, 25 micrograms per cubic meter*—An employee's exposure to beryllium and its compounds shall not exceed 25 micrograms per cubic meter, the acceptable maximum peak above the acceptable ceiling concentration, for a maximum duration of 30 minutes.

These exposure limits are repeated in 29 CFR 1926 for construction and were adopted from the American National Standards Institute (ANSI) standard, ANSI Z37.29–1970.

OSHA has specific beryllium requirements for welding and cutting on beryllium-containing base or filler metals in 29 CFR 1910.252(c)(8):

> Welding or cutting indoors, outdoors, or in confined spaces involving beryllium-containing base or filler metals shall be done using local exhaust ventilation and airline respirators unless atmospheric tests under the most adverse conditions have established that the workers' exposure is within the acceptable concentrations defined by 29 CFR 1910.1000. In all cases, workers in the immediate vicinity of the welding or cutting operations shall be protected as necessary by local exhaust ventilation or airline respirators.

These requirements are repeated in 29 CFR 1926 for construction activities. In addition, OSHA Technical Manual CPL 2-2.20B references beryllium in Chapter 1, "Personal Sampling for Air Contaminants," Appendix 1–E, "Sampling for Special Analyses," under "Samples Analyzed by Inductively Coupled Plasma" and in Chapter 2, "Sampling for Surface Contamination," which suggests swipe sampling of surfaces since accumulated toxic materials such as beryllium "may become suspended in air, and may contribute to airborne exposures. Bulk and wipe samples are used as aids in determining this possibility."

NIOSH Recommendation for Beryllium

The NIOSH Recommended Exposure Level (Ceiling) is 0.5 $\mu g/m^3$.

NIOSH also identifies beryllium as an occupational carcinogen.

American Conference of Governmental Industrial Hygienists Beryllium TLV

The ACGIH has established a threshold limit value (TLV) for beryllium and beryllium compounds. The TLV 8-hour TWA is 2 micrograms per cubic meter. The ACGIH lists beryllium and beryllium compounds as an A1 carcinogen, a confirmed human carcinogen. ACGIH explains this classification in their documentation of TLVs by indicating that the weight of evidence supports the view that beryllium is a confirmed human carcinogen but is of such low potency that only persons exposed to levels similar to those existing in the

Lorain and Reading plants in the 1940's would be at significant risk of developing lung cancer[1] (ACGIH 1997).

The ongoing medical surveillance program provides assurance that the processing level industrial hygiene monitoring measures are effective at detecting any beryllium exposure during beryllium operations. Worker exposure to beryllium from HE processing and testing would be the same as that experienced by the public and is discussed in section D.3.2.

D.2.2.4 *Worker Physical Safety Consequences*

Rates of accidents and injuries which are potentially within normal operations at LANL were projected by alternative on the basis of changes in the LANL worker population. Physical hazards include exposures to such hazards as slow leaks from compressed air cylinders of toxic gases such as acetylene, used in welding, or small "pony" bottles of specialized gases used in chemical processing or bench-scale research and development. Electrical hazards, industrial hazards associated with building maintenance and renovation, and ergonomic hazards are typical throughout LANL facilities and field sites. During 1995, reportable accidents and injuries occurred at a rate of 4.6 per 100 workers at LANL, and this rate was used in the SWEIS analyses to generate Table D.2.2.4–1. Although LANL has initiated a program to improve worker health and safety performance, no credit was taken for implementation of this program in the projections of accidents and injuries.

1. As an example, data for the Lorain plant found exposures ranging from 411 micrograms per cubic meter ($\mu g/m^3$) in the general area near a mix operation to 43,300 $\mu g/m^3$ in the breathing zone at an alloy operation.

TABLE D.2.2.4–1.—*Projected Recordable Cases per Alternative at LANL*

ALTERNATIVE	WORKER POPULATION	PROJECTED RECORDABLE CASES	PERCENT CHANGE FROM BASE CASE
Base Case	9,081	418	--
No Action	9,667	445	6.5
Expanded Operations	11,003	507	21.3
Reduced Operations	9,052	417	-0.2
Greener	9,656	445	6.5

D.3 ANALYSIS OF POTENTIAL PUBLIC HUMAN HEALTH CONSEQUENCES DUE TO THE CONTINUED OPERATION OF LANL

This section presents the detailed analyses performed with regard to the potential for the continued operation of LANL to affect public health.

D.3.1 Public Health Consequence Analysis

The analysis presented on human health consequences is extremely conservative. That is, DOE has used as a methodology to identify possible consequences based on maximum concentration estimates of radionuclides and chemicals in the environment, maximum exposure durations, and maximum estimates of ingestion or inhalation intake rates. The slope factors used to estimate carcinogenic risk and the reference doses used to estimate hazard indices, as well as the unit risk concentration used to evaluate outcomes were all established by EPA to be protective of human health, and therefore, include safety factors in order to avoid potential underestimation of impacts.

The conservatism is used in analysis of potential consequences because of the high degree of uncertainty associated with attempting to realistically estimate exposure, resulting dose, and resulting health effects. Therefore, the resulting values of risk (such as excess LCFs or hazard index) are believed to be worst-case consequences to a hypothetical receptor. The hypothetical receptor is not a person living in the community but an analytical construct representing a person who would be in the location of maximum concentrations of radionuclides or chemicals, take the maximum amounts of these contaminants into the person's body, and experience the worst outcome.

Uncertainties in public health consequence analysis include:

- Actual exposures to radionuclides and chemicals in each exposure pathway (inhalation, ingestion and immersion)
- Exposure durations to radionuclides and chemicals present in low concentrations in air, soils and sediments, water, and foodstuffs
- Variability among humans in reaction to exposure to radionuclides and chemicals
- Synergisms among chemicals/radionuclides in the exposed person, synergisms between chemical/radionuclides and natural phenomena (such as solar radiation and exposure to ultraviolet sources, as well as inhalation of radionuclides from LANL operations), and interactions between some chemicals/radionuclides and other stressors or behaviors such as smoking

D.3.1.1 *Inhalation Radiological Doses Estimated to the Public from LANL and Specific Key Facilities Under the Four Alternatives for Continued Operations*

The methods used to estimate the radiological dose from air emissions from specific facilities and from LANL as a site are summarized in sections 5.1.4 and 5.1.6 and are detailed in appendix B. The estimated doses to both the facility-specific and LANL-wide MEI are presented in Table D.3.1.1–1 for each of the four alternatives for continued operations. These values are also presented by alternative in sections 5.2.6.1 (No Action), 5.3.6.1 (Expanded Operations), 5.4.6.1 (Reduced Operations), and 5.5.6.1 (Greener). As detailed in section 5.1.6 and appendix D, section D.2, the ICRP methodologies for estimated cancer risk per rem dose received were applied to these estimates and are reported in chapter 5 in the referenced sections.

D.3.1.2 *Public Radiological Doses from Ingestion for all Four Alternatives*

The methodology for estimating the public doses through ingestion is described in section D.2.1.2. Because there is no release that would increase existing concentrations in the environmental media comprising the ingestion pathways (food, soil, sediment, water), the projected doses are the same for the baseline and all four alternatives. These are given in Table 5.2.6.1–2 for an average (50th percentile) intake of contaminated media, and in Table 5.2.6.1–3 for the worst-case (95th percentile) consumption of contaminated media.

D.3.2 Analysis of Public Health Consequences from High Explosives Testing Site Chemical Emissions

In applying the nonradiological air quality methodology as presented in section 5.1.4.1, three chemicals (depleted uranium, beryllium, and lead) were identified from one or more of four TAs (TA–14, TA–15, TA–36 and TA–39) in which high explosives are tested as being of sufficient concentrations to require human health analysis. While a few other metals were identified using the screen (appendix B, section B.2), their reference doses (EPA 1997b) were high, potential concentrations in air were overestimated using the conservative screening methodologies applied, and have low toxicities and low probabilities of carcinogenicity. Therefore, they were not quantitatively evaluated for human health consequences. These metals were:

- Aluminum
- Copper
- Iron
- Tantalum
- Tungsten

The modeling used to estimate exposures to the public from HE chemical emissions under the No Action and Expanded Operations Alternatives is presented in section 5.1.4.1 and detailed in appendix B (sections B.2.3.2 and B.2.3.3). (The quantities of expended materials were the same for the Reduced Operations and Greener Alternatives as for No Action.)

Tables D.3.2–1 (No Action, Reduced Operations, and Greener) and D.3.2–2 (Expanded Operations) present the results of the modeling performed to estimate the concentration of specific chemicals at the MEI location for each TA. The chronic daily uptake was calculated as presented in appendix D.2.1 for both the average uptake and worst-case uptake, using EPA's *Exposure Factors Handbook* (EPA 1997a). The hazard index is presented for uranium and lead, based on the reference dose give in EPA's Integrated Risk Information System (EPA 1997b). A hazard index of 1 or greater than one is considered indicative of a potential health hazard to exposed individuals. EPA has not published a reference dose for inhalation of beryllium. Therefore, a hazard index could not be calculated for beryllium.

TABLE D.3.2–1.—*Analysis of Public Health Consequences from Specific Chemicals Emitted from the High Explosives Test Areas (TA–14, TA–15, TA–36, and TA–39) in the No Action, Reduced Operations, and Greener Alternatives*[a,c]

TA–39	Beryllium	1.0	3.0E-5	< 1.0E-5	< 2.1E-9	< 4.2E-9	b	b
	Lead	1.0	3.0E-5	< 1.0E-5	< 2.1E-9	< 4.2E-9	< 4.9E-6	< 9.8E-6

Source: Appendix B, sections B.2.3.2 and B.2.3.3.

[a] Depleted uranium, beryllium, and lead were identified in the nonradiological air quality evaluation as requiring public health consequence analysis under the Expanded Operations Alternative. For the No Action, Reduced Operations, and Greener Alternatives, emissions were estimated as one-third that of the Expanded Operations emissions based on the annual expenditures of materials projected for these alternatives for continued HE testing.

[b] There is currently no reference dose for beryllium inhalation (EPA 1997b); therefore, no hazard index could be calculated. Based on the inhalation unit risk factor (EPA 1997b) of 2.4E-3 per μg/m^3, the maximum beryllium carcinogenic risk would be < 3.6E-8/year.

[c] Values rounded to 2 significant figures.

[a] Depleted uranium, beryllium, and lead were identified in the nonradiological air quality evaluation as requiring public health consequence analysis under the Expanded Operations Alternative.

[b] There is currently no reference dose for beryllium inhalation (EPA 1997b); therefore, no hazard index could be calculated. Based on the inhalation unit risk factor (EPA 1997b) of 2.4E-3 per μg/m^3, the beryllium carcinogenic risk would be approximately 3.6E-8/year.

[c] Values rounded to 2 significant figures.

D.3.3 Estimates of Dose and Risk from Radiological and Metallic Contaminants Potentially Ingested by Residents, Recreational Users of LANL Lands, and via Special Pathways

The methodology for estimating dose and risk from contaminants that could be ingested as or with food and water is given in section 5.1.6 and detailed in appendix D, section D.2.1.2. The data on which the estimates of ingestion and risk were based were environmental surveillance data, which are presented in appendix D, section D.3.5.

Each table presented in this section (Tables D.3.3–1 through D.3.3–50, provided as an attachment to this appendix) contains the concentration data used for calculations. The 95 percent UCL was used for the concentrations. The 95 percent UCL was determined as the average value, plus twice the standard deviation. In calculating the UCL, all samples of zero or negative value or less than the detection limit were rejected. This significantly increases the UCL, and especially so when a large fraction of the samples show no detectable contamination. In other words, in this conservative approach, a few samples that show measurable contamination will receive disproportionate weighting in the distribution. Both the average intake and worst-case intake were estimated using EPA's *Exposures Factors Handbook* (EPA 1997a). All dose conversion factors are given in the tables.

These tables represent the risk estimated from all alternatives based on ingestion. The risk factors used are conservative and represent the upper bound of the risk. The risk is uncertain and could be much smaller, as discussed in section D.1.1.8. Note that for ingestion pathways, exposure limits for exposure by inhalation are not applicable. There are no estimated differences in contaminant levels that would result from implementation of any of the four alternatives for continued operations. There is a discussion of concentrations of radiological and metallic contaminants in media in the region of Los Alamos versus background concentrations of these in the region presented in section D.3.4. Total risks estimated for ingestion are presented in chapter 5, specifically in section 5.2.6.1 (No Action).

D.3.3.1 *Potential Exposures to Tritium via Los Alamos Canyon*

As a result of recent studies and concerns with regard to tritium in groundwater from recent and historical releases in and near Los Alamos Canyon, this section briefly summarizes the present status of knowledge found in the LANL annual environmental reports.

In the past, Los Alamos Canyon received treated and untreated industrial effluents containing some radionuclides. In the upper reach of Los Alamos Canyon there were releases of treated and untreated radioactive effluents during the earliest Manhattan Project operations at TA–1 (late 1940's) and some release of water and radionuclides from the research reactors at TA–2. Los Alamos Canyon also received discharges containing radionuclides from the sanitary sewage lagoon system at LANSCE (formerly Los Alamos Meson Physics Facility) (TA–53). The low-level radioactive waste stream was separated from the sanitary system at TA–53 in 1989 and directed into a total retention evaporation lagoon. An industrial liquid waste treatment plan that served the old plutonium processing facility at TA–21 discharged effluent containing radionuclides into DP Canyon, a tributary to Los Alamos Canyon, from 1952 to 1986.

The reach of Los Alamos Canyon within the LANL boundary currently carries flow from the Los Alamos Reservoir (west of LANL), as well as National Pollutant Discharge Elimination System (NPDES)-permitted effluents from TA–2, TA–53, and TA–21. Infiltration of NPDES-permitted effluents and natural runoff from the stream channel maintains a shallow body of groundwater in the alluvium of Los Alamos Canyon within the LANL boundary west of State Road 4. Groundwater levels are highest in late spring from snowmelt runoff and in late summer from thundershowers. Water levels decline during the winter and early summer when runoff is at a minimum. Depth to water is typically in the range of 4 feet to 15 feet (1.2 meters to 4.6 meters). Alluvial perched groundwater also occurs in the lower portion of Los Alamos Canyon on Pueblo of San Ildefonso lands. This alluvium is not continuous with the alluvium within LANL boundaries, and can be sampled utilizing wells installed by the Bureau of Indian Affairs.

The EPA primary drinking water standard and the New Mexico livestock watering standard are both 20,000 picocuries per liter. No tritium has been detected in surface or groundwater samples using the EPA-specified method with a detection limit of 700 picocuries per liter. LANL reported a sample of surface water with 200 picocuries per liter in 1995, and samples ranging from 78 to 428 picocuries per liter in 1994. Intermediate groundwater in 1994 and 1995 had a concentration of only 27 picocuries per liter. However, these values may be meaningless, in that the past detection limit may actually be 800 to as much as 2,000 picocuries per liter, as discussed in section 5 of the 1995 annual environmental surveillance report (LANL 1996b). In any event, the tritium concentrations are well below the standards for drinking water. Tritium content of sediments could not be measured due to insufficient moisture content.

Special study samples analyzed by Miami University with a detection limit of 0.3 picocuries per liter have demonstrated minimal recharge of the regional aquifer by surface waters. Details of special and routine measurements of tritium are found in the 1996 environmental surveillance report (LANL 1997).

D.3.3.2 *Mortandad Canyon*

Mortandad Canyon has a small drainage area that heads at TA–3. Its drainage area currently receives inflow from natural precipitation and a number of NPDES-permitted effluents, including one from the existing Radioactive Liquid Waste Treatment Facility at TA–50. The TA–50 facility began operations in 1963. In six cases during the period from 1993 through 1995, the derived concentration guide (DCG) was exceeded for: americium-241 in 1993; americium-241 and plutonium-238 in 1994; and plutonium-238, plutonium-239, plutonium-240, and americum-241 in 1995. For each of these years, the effluent nitrate concentrations exceeded the New Mexico groundwater standard of 10 milligrams per liter (nitrate as nitrogen). The groundwater standard applies because the TA–50 effluent infiltrates the alluvium in the canyon. In order to address these problems, LANL is working to upgrade the TA–50 treatment process. These effluents infiltrate the stream channel and maintain a saturated zone in the alluvium extending about 2.2 miles (3.5 kilometers) downstream from the TA–50 NPDES-permitted outfall. The easternmost extent of saturation is on site, about 1 mile (1.6 kilometers) west of the LANL boundary with the Pueblo of San Ildefonso. Surface flow in the drainage has not reached the Pueblo since observations began in the early 1960's.

Radioanalytical results for sediments collected from Mortandad Canyon in 1996 were modeled using the RESRAD model, version 5.61 (LANL 1997). The pathways evaluated are the external gamma pathway from radioactive material deposited in the sediments, the inhalation pathway from materials resuspended by winds, and the soil ingestion pathway. Because water in the canyon is not used for drinking water or irrigation, and there are no cattle grazing in the canyon or gardens in the canyon, the drinking water, meat ingestion, and fruit/vegetable ingestion pathways were not considered.

The RESRAD model was run for each sampled location and for the entire canyon system, with 10 to 14 samples per analyte collected throughout the canyon. For modeling purposes, it is assumed that the area of interest around each monitored location is 1,076 square feet (100 square meters). The site is part of an industrial complex where access to the monitored location is somewhat limited; thus, the amount of time a person spends in the canyon is limited to approximately 87 hours per year (Robinson and Thomas 1991), and there is no cover material over the site of interest that would reduce external exposure to radionuclides. The input parameters for the RESRAD model are summarized in LANL 1997. RESRAD calculates the daughter radionuclides based on the initial radionuclide concentration and time since placement of material.

The TEDE (i.e., the sum of the effective dose equivalents from the external gamma, and the inhalation and soil ingestion pathways) is presented in Table D.3.3.2–1. For comparison, the 1995 TEDE for each monitoring location is shown also. The TEDE, using the average concentration of all monitoring locations in Mortandad Canyon, is 6.0 millirem. The error term associated with this average value is extremely large, reflecting the high degree of variability in the concentrations throughout the canyon. In 1996, the average TEDE plus twice the error term (Table D.3.3.2–1) ranged from 0.19 millirem near the Chemistry and Metallurgy Research (CMR) Building to 27 millirem at the GS–1 sampling location.

TABLE D.3.3.2–1.—*Total Effective Dose Equivalent[a] for Mortandad Canyon (mrem)*

LOCATION	1996		1995	
Near CMR Building	0.16	(± 0.032)[b]	0.10	(± 0.14)[b]
West of GS–1	3.3	(± 0.60)[b]	0.17	(± 0.081)[b]
GS–1	24	(± 3.4)[b]	37	(± 5.9)[b]
MCO–5	21	(± 3.2)[b]	19	(± 3.3)[b]
MCO–7	8.8	(± 1.4)[b]	4.3	(± 0.95)[b]
MCO–9	0.78	(± 0.21)[b]	0.62	(± 0.20)[b]
MCO–13 (A–5)	0.65	(± 0.19)[b]	0.43	(± 1.1)[b]
A–6	0.41	(± 0.097)[b]	0.79	(± 1.2)[b]
A–7	0.36	(± 0.072)[b]	0.19	(± 0.10)[b]
A–8	—[c]		0.30	(± 0.15)[b]
SR–4 (A–9)	0.19	(± 0.057)[b]	0.17	(± 0.088)[b]
A–10	—[c]		0.061	(± 0.028)[b]
Rio Grande (A–11)	0.16	(± 0.12)[b]	0.10	(± 0.054)[b]
Average for Entire Mortandad Canyon	6.0	(± 22)[b]	6.8	(± 0.30)[b]

[a] Based on results from RESRAD (version 5.61) using three exposure pathways: ingestion, inhalation, and external.
[b] ±2 sigma in parenthesis
[c] No sample collected at these locations in 1996.

The maximum TEDE for monitoring sites surrounding the GS–1 site (i.e., west of GS–1, MCO–5, MCO–7, and MCO–9) increased in 1996 over the 1995 values. These five monitoring locations represent 96 percent of the 1996 maximum TEDE for the entire canyon system. The only radionuclide that contributed more than 5 percent to the TEDE at these locations is cesium-137 for each of the five sites. For the other monitoring locations (i.e., near the CMR Building, MCO–13 [A–5], A–6, A–7, A–9, and A–11), the naturally occurring radionuclides of uranium, and strontium-90 and cesium-137 from nuclear atmospheric testing contributed more than 5 percent to the TEDE at these monitoring locations. Averaged over the entire canyon system, cesium-137 and americium-241 contributed more than 5 percent to the canyon TEDE. The external pathway contributed more than 88 percent (with the cesium-137 contribution being more than 86 percent) to the total TEDE for the entire canyon system. Because there is a pathway approximately 10 feet (3 meters) from the stream channel and the external component falls off with distance from the source, the estimated TEDE is reduced to approximately 6 millirem in a year (i.e., 2.7 millirem from the external pathway and 3.3 millirem from all other pathways considered).

TABLE D.3.3–1.—*Ingestion of Radioactive Isotopes from LANL Supply Wells for an Off-Site Los Alamos County Resident (From ESR 1991–1996 Data, see Table D.3.5–2)*

Note: gray shaded cells in Carcinogenic Risk columns have no known human chemical cancer risk.

TABLE D.3.3–2.—*Ingestion of Metals in LANL Supply Wells to Off-Site Los Alamos County Residents (From ESR 1991–1996 Data, see Table D.3.5–2)*-Continued

Groundwater Ingestion Factors

Intake (mg/kg-day) = (CW x IR x EF x ED x CF)/(BW x AT)

Note: modified from 1989, exhibit 6-12, pg. 6-36.

Value	Units	Parameter
e.g., B3	µg/L	CW = LANL Supply Well concentration
1.51E+00	L/day	IR = **Average-Case** ingestion rate
365	days/yr	EF = **Average-Case** exposure frequency
2.44E+00	L/day	IR = **Worst-Case** ingestion rate
365	days/yr	EF = **Worst-Case** exposure frequency
75	yr	ED = Exposure duration
1.00E-03	mg/µg	CF = Conversion factor
71.8	kg	BW = Body weight
27375	d	AT = ED* 365 days

Note: 550 liters per year yields 1.51 liters per day for Average-Case.
Note: 891 liters per year yields 2.44 liters per day for Worst-Case.

[1] Arsenic concentrations ranged from 2 to 3 µg/L in 3 of 4 samples analyzed with a mean of 2.67 µg/L for detected values.
Note: gray shaded cells in UCL column have no 95% UCL - maximum value used.
Note: gray shaded cells in Slope Factor column have no known human chemical cancer risk.
Note: gray shaded cells in Carcinogenic Risk columns have no known human chemical cancer risk.

TABLE D.3.3–4.—*Ingestion of Metals in Supply Well LA-5 for an Off-Site Totavi Resident (From ESR 1991–1996 Data, see Table D.3.5–3)*-Continued

Groundwater Ingestion Factors

Intake (mg/kg-day) = (CW x IR x EF x ED x CF)/(BW x AT)

Note: modified from EPA 1989, exhibit 6-12, pg. 6-36.

Value	Units	Parameter
e.g., B3	µg/L	CW = LA-5 supply well concentration
1.51E+00	L/day	IR = **Average-Case** ingestion rate
365	days/yr	EF = **Average-Case** exposure frequency
2.44E+00	L/day	IR = **Worst-Case** ingestion rate
365	days/yr	EF = **Worst-Case** exposure frequency
75	yr	ED = Exposure duration
1.00E-03	mg/µg	CF = Conversion factor
71.8	kg	BW = Body weight
27375	d	AT = ED* 365 days

Note: 550 liters per year yields 1.51 liters per day for Average-Case.
Note: 891 liters per year yields 2.44 liters per day for Worst-Case.

TABLE D.3.3–5.—*Ingestion of Radioactive Isotopes from San Ildefonso Supply Wells for an Off-Site Non-Los Alamos County Resident (From ESR 1991–1996 Data, see Table C-6 but without LA-5 Well)*

[1] Arsenic concentrations ranged from 2 to 41 µg/L in 44 of 48 samples analyzed with a mean of 9.07 µg/L for detected values.
[2] Beryllium concentrations ranged from 1 to 17 µg/L in 6 of 48 samples analyzed with a mean of 7 µg/L for detected values.
Note: gray shaded cells in UCL column have no 95% UCL - maximum value used.
Note: gray shaded cells in Slope Factor column have no known human chemical cancer risk.
Note: gray shaded cells in Carcinogenic Risk columns have no known human chemical cancer risk.

Groundwater Ingestion Factors

Intake (mg/kg-day) = (CW x IR x EF x ED x CF)/(BW x AT)

Note: modified from EPA 1989, exhibit 6-12, pg. 6-36.

Value	Units	Parameter
e.g., B3	µg/L	CW = San Ildefonso supply well concentration
1.51E+00	L/day	IR = **Average-Case** ingestion rate
365	days/yr	EF = **Average-Case** exposure frequency
2.44E+00	L/day	IR = **Worst-Case** ingestion rate
365	days/yr	EF = **Worst-Case** exposure frequency
75	yr	ED = Exposure duration
1.00E-03	mg/µg	CF = Conversion factor
71.8	kg	BW = Body weight
27375	d	AT = ED* 365 days

Note: 550 liters per year yields 1.51 liters per day for Average-Case.
Note: 891 liters per year yields 2.44 liters per day for Worst-Case.

TABLE D.3.3–7.—*Ingestion of Radioactive Isotopes in Surface Water for a Resident Recreational User (From ESR 1991–1996 Data, see Table C-2)*

ANALYTE	95% UCL (pCi/L)	DOSE CONVERSION FACTOR (rem/pCi)	AVERAGE-CASE DOSE (rem/year)	WORST-CASE DOSE (rem/year)
Americium-241	1.20E+00	4.50E-06	2.88E-05	4.67E-05
Cesium-137[1]	2.49E+01	5.00E-08	6.64E-06	1.08E-05
Plutonium-238	1.10E+00	3.80E-06	2.23E-05	3.61E-05
Plutonium-239 and Plutonium-240	1.00E+01	4.30E-06	2.29E-04	3.72E-04
Strontium-90	2.40E+02	1.30E-07	1.66E-04	2.70E-04
Tritium	7.70E+00	6.30E-11	2.59E-09	4.19E-09
Uranium[2]	2.41E+00	2.60E-07	3.35E-06	5.42E-06
			Average-Case	**Worst-Case**
Total Dose (rem/yr)			4.57E-04	7.40E-04
Cancer Risk yr^{-1}			2.28E-07	3.70E-07

[1] Cesium-137 from ESR 1993–1996 data (see text).
[2] Uranium was converted using the formula from Fresquez et al. 1996, Appendix B, pg 36 (see below).

Average-Case Consumption	
2.78E-02 L/hr	=ingestion rate per hour
8 hr/event	=number of hours per visit
24 events/yr	=number of visits per year
5.33E+00 L/yr	=number of liters per year

Worst-Case Consumption	
4.50E-02 L/hr	=ingestion rate per hour
8 hr/event	=number of hours per visit
24 events/yr	=number of visits per year
8.64E+00 L/yr	=number of liters per year
1 yr	=exposure duration

Note: 0.5 liters per day over 18 hrs yields 2.78E-02 L/hr for Average-Case.
Note: Average case increased by 1.62 yields 4.5E-02 L/hr for Worst-Case.

Uranium Conversion:		**U=**	**3.4**	**µg/L**
pCi U isotope / L water = µg total Uranium/L water X RMA X SA X CF				
RMA = relative mass abundance (g isotope per g total U)				
SA = specific activity (pCi/g)				
CF = conversion factor (1E-06 g/µg)			**RMA**	**SA**
U-238 =	1.13E+00 pCi/L		0.9928	3.35E+05

TABLE D.3.3–8.—*Ingestion of Metals in Surface Water to Resident Recreational User (From ESR 1991–1996 Data, see Table C-2)*-Continued

Surface Water Ingestion Factors - Resident Recreational User

Intake (mg/kg/day) = (CW x IR x ET x EF x ED x CF)/(BW x AT)

Note: modified from EPA 1989, exhibit 6-12, pg. 6-36.

Value	Units	Parameter
e.g., B3	µg/L	CW = On-site concentration
2.78E-02	L/hr	IR = **Average-Case** ingestion rate (0.5 L / 18 hours)
8	hr/event	ET = **Average-Case** exposure time
24	events/yr	EF = **Average-Case** exposure frequency
4.50E-02	L/hr	IR = **Worst-Case** ingestion rate (0.5 L * 1.62 / 18 hours)
8	hr/event	ET = **Worst-Case** exposure time
24	events/yr	EF = **Worst-Case** exposure frequency
75	yr	ED = Exposure duration
1.00E-03	mg/µg	CF = Conversion factor
71.8	kg	BW = Body weight
27375	d	AT = ED* 365 days

TABLE D.3.3–9.—*Ingestion of Radioactive Isotopes in Surface Water for a Nonresident Recreational User (From ESR 1991–1996 Data, see Table C-2)*

ANALYTE	95% UCL (pCi/L)	DOSE CONVERSION FACTOR (rem/pCi)	AVERAGE-CASE DOSE (rem/year)	WORST-CASE DOSE (rem/year)
Americium-241	1.20E+00	4.50E-06	1.08E-05	1.75E-05
Cesium-137[1]	2.49E+01	5.00E-08	2.49E-06	4.03E-06
Plutonium-238	1.10E+00	3.80E-06	8.36E-06	1.35E-05
Plutonium-239 and Plutonium-240	1.00E+01	4.30E-06	8.60E-05	1.39E-04
Strontium-90	2.40E+02	1.30E-07	6.24E-05	1.01E-04
Tritium	7.70E+00	6.30E-11	9.70E-10	1.57E-09
Uranium[2]	2.41E+00	2.60E-07	1.26E-06	2.03E-06
			Average-Case	**Worst-Case**
Total Dose (rem/yr)			1.71E-04	2.78E-04
Cancer Risk yr^{-1}			8.57E-08	1.39E-07

[1] Cesium-137 from ESR 1993–1996 data (see text).
[2] Uranium was converted using the formula from Fresquez et al. 1996, Appendix B, pg. 36 (see below).

Average-Case Consumption	
2.78E-02 L/hr	=ingestion rate per hour
6 hr/event	=number of hours per visit
12 events/yr	=number of visits per year
2.00E+00 L/yr	=number of liters per year

Worst-Case Consumption	
4.50E-02 L/hr	=ingestion rate per hour
6 hr/event	=number of hours per visit
12 events/yr	=number of visits per year
3.24E+00 L/yr	=number of liters per year
1 yr	=exposure duration

Note: 0.5 liters per day over 18 hrs yields 2.78E-02 L/hr for Average-Case.
Note: Average case increased by 1.62 yields 4.5E-02 L/hr for Worst-Case.

Uranium Conversion:		**U=**	**3.4**	**µg/L**
pCi U isotope / L water = µg total Uranium/L water X RMA X SA X CF				
RMA = relative mass abundance (g isotope per g total U)				
SA = specific activity (pCi/g)				
CF = conversion factor (1E-06 g/µg)			**RMA**	**SA**
U-238 =	1.13E+00 pCi/L		0.9928	3.35E+05
U-235 =	5.29E-02 pCi/L		0.0072	2.16E+06
U-234 =	1.23E+00 pCi/L		0.000058	6.24E+09
Total U Activity =	**2.41E+00 pCi/L**

On-Site Soil Ingestion Factors - Nonresident Recreational User

Intake (mg/kg/day) = (CW x IR x ET x EF x ED x CF)/(BW x AT)

Note: modified from EPA 1989, exhibit 6-12, pg. 6-36.

Value	Units	Parameter
e.g., B3	mg/kg	CW = On-site concentration
5.56E+00	mg/hr	IR = **Average-Case** ingestion rate
6	hr/event	ET = **Average-Case** exposure time
12	events/yr	EF = **Average-Case** exposure frequency
2.22E+01	mg/hr	IR = **Worst-Case** ingestion rate
6	hr/event	ET = **Worst-Case** exposure time
12	events/yr	EF = **Worst-Case** exposure frequency
1	yr	ED = Exposure duration
1.00E-06	kg/mg	CF = Conversion factor
71.8	kg	BW = Body weight

Note: 100 mg per day over 18 hrs yields 5.56 mg per hour for Average-Case.
Note: 400 mg per day over 18 hrs yields 22.2 mg per hour for Worst-Case.

TABLE D.3.3–21.—*Ingestion of Radioactive Isotopes in Perimeter Sediment for an Off-Site Resident (Nonspecific County) (From ESR 1991–1996 Data, see Table C-4)*

ANALYTE	95% UCL (pCi/g)	DOSE CONVERSION FACTOR (rem/pCi)	AVERAGE-CASE DOSE (rem/year)	WORST-CASE DOSE (rem/year)
Americium-241	2.20E-01	4.50E-06	3.61E-05	1.45E-04

Cesium-137	1.80E+01	5.00E-08	3.60E-07	1.44E-06
Plutonium-238	1.70E+00	3.80E-06	2.58E-06	1.03E-05
Plutonium-239 and Plutonium-240	3.70E+00	4.30E-06	6.36E-06	2.55E-05
Strontium-90	1.60E+00	1.30E-07	8.32E-08	3.33E-07
Tritium[1]	3.11E+00	6.30E-11	7.84E-11	3.14E-10
Uranium[2]	2.70E+00	2.60E-07	2.81E-07	1.12E-06
			Average-Case	**Worst-Case**
Total Dose (rem/yr)			1.65E-05	6.60E-05
Cancer Risk yr^{-1}			8.26E-09	3.30E-08

[1] Tritium was converted from pCi/mL using the formulas from Fresquez, 1996 et al. Appendix B, pg. 36 (see below).
[2] Uranium was similarly converted (see below).

Average-Case Consumption	
5.56E+00 mg/hr	=ingestion rate per hour
6 hr/event	=number of hours per visit
12 events/yr	=number of visits per year
4.00E-01 g/yr	=number of grams per year

Worst-Case Consumption	
2.22E+01 mg/hr	=ingestion rate per hour
6 hr/event	=number of hours per visit
12 events/yr	=number of visits per year
1.60E+00 g/yr	=number of grams per year
1 yr	=exposure duration

Note: 100 mg per day over 18 hrs yields 5.56 mg/hr for Average-Case.
Note: 400 mg per day over 18 hrs yields 22.2 mg/hr for Worst-Case.

TABLE D.3.3–25.—*Ingestion of Radioactive Isotopes in Sediment for a Nonresident Recreational User (From ESR 1991–1996 Data, see Table C-4)*-Continued

Tritium Conversion:	**H^3=**	**28**	**pCi/mL**
pCi/g = pCi/mL X (fraction soil moisture/soil moisture density X [1-fraction soil moisture])			
Fraction soil moisture = 10%

Note: gray shaded cells in Slope Factor column have no known human chemical cancer risk.
Note: gray shaded cells in Carcinogenic Risk columns have no known human cancer risk.

On-Site Sediment Ingestion Factors - Nonresident Recreational User

Intake (mg/kg/day) = (CW x IR x ET x EF x ED x CF)/(BW x AT)

Note: modified from EPA 1989, exhibit 6-12, pg. 6-36.

Value	Units	Parameter
e.g., B3	mg/kg	CW = On-site concentration
5.56E+00	mg/hr	IR = **Average-Case** ingestion rate
6	hr/event	ET = **Average-Case** exposure time
12	events/yr	EF = **Average-Case** exposure frequency
2.22E+01	mg/hr	IR = **Worst-Case** ingestion rate
6	hr/event	ET = **Worst-Case** exposure time
12	events/yr	EF = **Worst-Case** exposure frequency
1	yr	ED = Exposure duration
1.00E-06	kg/mg	CF = Conversion factor
71.8	kg	BW = Body weight
365	d	AT = ED* 365 days

Note: 100 mg per day over 18 hrs yields 5.56 mg per hour for Average-Case.
Note: 400 mg per day over 18 hrs yields 22.2 mg per hour for Worst-Case.

TABLE D.3.3–27.—*Ingestion of Honey for Off-Site Residents (Note: Includes LANL 1990–1994 Los Alamos and White Rock County Data for Los Alamos County and San Ildefonso Data for Non-Los Alamos County Resident) (Foodstuffs Database 1990–1994, see Table D.3.5–6)*

D.3.4 Comparison of Concentrations of Selected Radionuclides and Metals in Regional and LANL Perimeter/On-Site Samples of Environmental Media

Table D.3.4–1 summarizes an analysis of differences between samples taken on site or at the perimeter of LANL versus those taken in the general region of northern New Mexico. (The network of annual sampling stations for surface water, groundwater, and sediment surveillance includes a set of regional [or background] stations and a group of stations near or within the LANL boundary—these data are addressed in section D.3.5 and are provided in appendix C.) The concentrations of plutonium-239 were found to be elevated from that of the region in the media at the perimeter of LANL. Values for fruits grown on site, honey from on-site TAs, and deer (road kills) on site showed elevated plutonium-239 concentrations. These foodstuffs are not consumed, but were collected to determine concentrations in biological media in known contaminated areas of the LANL reservation.

D.3.4.1 *Arsenic*

For most people, the primary mode of arsenic exposure is from food and water consumption. The average ingestion rate for members of the public is about 25 to 50 micrograms per day in food alone (ATSDR 1989 and EPA 1997b). Typically, exposure from water is less. The estimated maximum exposures (95th percentile) to arsenic from ingestion near LANL are:

- Store-bought vegetables (Table D.3.3–37): approximately 31 micrograms per day
- On-site fruit (not consumed, Table D.3.3–49): approximately 61 micrograms per day
- Fish (special pathways consumption rate, Table D.3.3–43): approximately 68 micrograms per day
- Surface waters (Table D.3.3–8): approximately 0.24 microgram per day
- NPDES discharge (Table D.3.3–12): approximately 0.62 microgram per day
- Groundwater (Los Alamos supply, Table D.3.3–2): approximately 98 micrograms per day
- Groundwater (San Ildefonso supply, Table D.3.3–6): approximately 53 micrograms per day

The primary source of arsenic in food and water sources in the LANL area are naturally occurring in soil and basalt minerals and are almost entirely inorganic in form (LANL 1997) The concentrations of arsenic in groundwater supply wells are not significantly different between Los Alamos and San Ildefonso (appendix C).

The main uses of arsenic in the U.S. are in pesticide formulation. LANL does not utilize arsenic in manufacturing levels in its research and development or processing activities. Arsenic is known to be beneficial or necessary for human metabolism in micro-quantities (ATSDR 1989).

When amounts less than 200 to 250 micrograms per day of arsenic are ingested, the human body can detoxify the inorganic form of arsenic by "methylation" (that is, by the addition of methyl groups to the ionic form). This does provide protection from toxic effects of inorganic arsenic. It does not necessarily protect against carcinogenesis. One hypothesis suggests that the natural methylation are "stolen" from deoxyribonucleic acid (DNA) synthesis making chromosome damage more probable (CLAWS 1997).

The single most characteristic system of ingestion exposure to inorganic arsenic is a pattern of skin abnormalities including the

[a] These values are for samples collected in known contaminated areas on site. These foodstuffs are not consumed as home produce and are not allowed to be placed into commerce.

appearance of dark and light spots on the skin and small "corns" on the palms, soles, and trunk. While these skin changes are not considered to be a health concern in their own right, some may progress toward skin cancer. In addition, arsenic ingestion has been reported to increase the risk of certain cancers: liver, bladder, kidney, and lung. Organic forms of arsenic such as that found in fish seem to be less toxic than inorganic forms (ATSDR 1989).

EPA has recently held public meetings regarding its activity to develop proposed National Primary Drinking Water Regulations. The current Interim Water Primary Standard for arsenic is 50 micrograms per liter in drinking water and was established in 1976 to protect against skin cancer. This standard was scheduled for finalization with the other phase II compounds in 1991. However, due to new evidence (from Taiwanese epidemiological studies) implicating arsenic in the development of other and more serious internal cancers, the maximum contaminant level (MCL) for arsenic was delayed.

EPA has discussed in public meetings a new MCL between 0.5 and 2 micrograms per liter based on a multistage, linear modeling study of potential human risk. Based on this model, a 1 in 1,000,000 cancer risk level would be 2 parts per billion (2 parts per billion or 2 microgram per liter). The groundwater supplies used in Los Alamos County and San Ildefonso have a 95th percentile UCL of 40 micrograms per liter and 22 micrograms per liter, respectively, based on the 1991 to 1996 LANL Environmental Surveillance Reports. The concentrations are lower than the current MCL for arsenic of 50 micrograms per liter. These concentrations are in and above the ranges EPA is considering in the new MCL for arsenic. While LANL operations do not affect arsenic risk to the public, the range of arsenic concentrations in the region of LANL are in the range that may be potentially be in the range for carcinogenesis at a rate in excess of 1 in 1,000,000.

D.3.4.2 *Beryllium*

Beryllium is a hard grayish metal that, in nature, is usually found in mineral compounds, especially in coal and in volcanic rock and weathered volcanic soils. Some beryllium is soluble but most is insoluble. Most soil beryllium-containing minerals have low solubilities (ATSDR 1993).

Ingestion risks from beryllium are very low, but beryllium is a suspected human carcinogen (EPA 1997b). The oral (ingestion) reference dose (RfD) is limited to soluble beryllium salts and is 5 x 10^{-3} milligrams per kilograms-day. The estimated maximum exposures (95th percentile) from ingestion of total beryllium near LANL range from 10^{-3} to 10^{-5} milligrams per kilograms-day. The concentrations of beryllium in the waters in the LANL area are in the 1 to 10 micrograms per liter range.

The primary risk from beryllium is from inhalation, which can lead to Chronic Beryllium Disease. Beryllium workers at LANL are protected from beryllium in the workplace under the Guidance for Implementation of DOE Order 440.1 section addressing "Chronic Beryllium Disease Prevention Program." The potential consequences of beryllium emissions from HE testing at LANL is discussed in sections 5.2.6.1 and 5.3.6.1.

D.3.4.3 *Lead*

Lead is an element found throughout the Earth's crust. Inorganic lead compounds are much less toxic than organic lead compounds. Exposure is primarily by inhalation and ingestion. Exposure to environmental media containing lead is the primary source of elevated blood levels of lead in children. Lead-containing paint in the home is the principal environmental lead source. At levels less than 20 micrograms per deciliter in the blood of a pregnant woman for even a short term (less than 14 days), low birth rate and learning impairment in the infant may occur. Longer exposures of young children can result in reduced IQ and slowed growth rates. Brain and kidney damage in children can result from blood levels of lead between 70 and 100 micrograms per deciliter.

Concentrations of lead in soil/sediments and water are in the range of 10 to 100 milligrams per kilogram and 1 to 10 micrograms per liter, respectively. In Los Alamos County supply wells, the concentrations of lead are not significantly different from the oral reference dose (1.4 x 10^{-3} milligrams per kilograms-day). Lead in environmental media near LANL is not significantly different from that in the entire region. Concentrations of lead are not expected to be affected by continued LANL operations, even in the Expanded Operations Alternative for HE testing (sections 5.2.6.1 and 5.3.6.1). Although lead is a suspected carcinogen, EPA has not established an oral or inhalation slope factor for risk estimation.

D.3.5 Data Used in the Human Health Analysis

Data used for estimating dose and risk for various pathways and receptors are provided in Tables C–1, C–2, C–4, and C–6 in appendix C as well as the tables included in this section (Tables D.3.5–1 through D.3.5–16). These data were taken from sampling locations that form the network of monitors on and around LANL. These data are routinely reported in the LANL annual environmental surveillance reports (such as LANL 1994).

Not all data sets were collected for the same years. Each data table in this SWEIS specifies the years reported.

Environmental restoration site data are presented in Tables C–8 and C–9 in appendix C. In general, these were not used to estimate risk to MEIs because they are in known contaminated areas that are not subject to public exposure. In cases where use of this data was considered appropriate, the discussion of the methodology and analysis identified the data used.

Silica	mg/l	4	40.0	42.0	43.0	44.0
Sulfate	mg/l	4	4.0	5.6	6.5	7.8
Total Dissolved Solids	mg/l	4	140.0	160.0	180.0	200.0

[a] Analytes and number of detected analyses from LA–5 only.
[b] pCi/l is picocuries per liter, nCi/l is nanocuries per liter, µg/l is micrograms per liter, and mg/l is milligrams per liter.
[c] Upper confidence limit (UCL) not calculated for number of detected analyses less than two.

TABLE D.3.5–4.—*NPDES Analyte Summary Statistics Used in Consequence Analysis (ESH NPDES Data, 1994 to 1996)*

ANALYTE[a]	UNITS[b]	DETECTED	ANALYZED	MINIMUM	MEAN	MAXIMUM	95% UCL
Aluminum (T)	mg/l	40	117	0.06	0.24	1.2	0.75
Arsenic (T)	mg/l	60	99	0.0016	0.0062	0.072	0.026
Boron (T)	mg/l	118	118	0.01	0.082	2.5	0.54
Cadmium (T)	mg/l	27	117	0.0001	0.0015	0.023	0.01
Chromium (T)	mg/l	79	115	0.004	0.012	0.07	0.038
Cobalt (T)	mg/l	23	118	0.0005	0.0062	0.028	0.017
Copper (T)	mg/l	69	115	0.004	0.044	0.59	0.25
Lead (T)	mg/l	24	117	0.0002	0.0084	0.045	0.032
Mercury (T)	mg/l	6	117	0.0003	0.00063	0.0017	0.0017
Radium-226, Radium-228	pCi/l	117	117	0.02	1.7	18.503	7.3
Selenium (T)	mg/l	18	118	0.001	0.0021	0.0063	0.0046
Tritium	pCi/l	65	118	6	2,900	134143	37,000
Vanadium (T)	mg/l	111	117	0.003	0.018	0.12	0.047
Zinc (T)	mg/l	106	117	0.016	0.082	1.2	0.34

[a] (T) signifies that the total amount of the analyte in the sample was measured (both the dissolved amount and the amount adsorbed to suspended particles).
[b] mg/l is milligrams per liter; pCi/l is picocuries per liter.

[a] On-site, perimeter and regional designations in accordance with Environmental Surveillance Program.
[b] pCi/g is picocuries per gram, pCi/ml is picocuries per milliliter, µg/g is micrograms per gram.
[c] Number of detected analyses not available. Values represent the number of means (from Fresquez et al. 1997).
[d] Number of analyses not available.
[e] Minimum and maximum values not available.
[f] Values are means for radiochemical constituents and mean of means for trace metal constituents.

APPENDIX E
CULTURAL RESOURCES

E.1 OVERVIEW

This appendix provides supplemental information regarding the prehistoric and historic cultural resources present at LANL, including traditional cultural properties (TCP), that may be affected by ongoing and proposed LANL operations. Cultural resources are any prehistoric or historic sites, buildings, structures, districts, or other places or objects (including biota of importance) considered to be important to a culture, subculture, or community for scientific, traditional, or religious purposes, or for any other reason. While not all cultural resources need to be preserved, those with cultural significance require identification and protection so that future generations may be informed and enriched by the past.

In section E.2, information is presented regarding the results of previous cultural resource research in the LANL region. Section E.3 provides a summary of the background of the LANL region that led to a classification system developed for LANL, based on the regional cultural context of prehistoric and historic development on the Pajarito Plateau and the traditional cultures of the region. Section E.4 contains an overview of the major federal and state regulatory requirements concerning cultural resources. Section E.5 contains information regarding the research methods employed to identify, document, and assess the cultural resources likely to be affected by LANL operations. Detailed information is provided in section E.6 on the existing cultural resources that are protected by the *National Historic Preservation Act* (NHPA) (16 U.S.C. §470). Section E.7 is a list of references used in conducting this assessment and preparing this report.

Cultural resources are location-specific; therefore, the cultural resource study area is defined as the area within LANL's physical boundaries and those areas surrounding LANL that may be potentially affected by LANL activities. A broader study area has been defined for the identification and assessment of TCPs, because the TCP evaluation includes an assessment of historical use and value placed on cultural resources by existing cultural groups with current or ancestral ties to the LANL region, irrespective of their current locations.

E.2 PREVIOUS STUDY OF CULTURAL RESOURCES IN THE LANL REGION

The following subsections contain a history and summaries of previous studies of cultural resources in the LANL region.

E.2.1 Studies of Prehistoric Resources

The Pajarito Plateau is among the most intensively studied archaeological regions in the U.S. due in part to the density of archaeological sites. Archaeological study began in 1880 when Adolph Bandelier visited the Puye ruins and Rito de los Frijoles, measuring and taking notes on the ruins (Bandelier 1892). A survey of the Pajarito Plateau was made by Edgar Lee Hewett in 1896 and the results were published in 1904 (Hewett 1904). In 1916, Hewett helped establish Bandelier National Monument (BNM) as one of the first facilities in the region to protect outstanding archeological ruins (Steen 1977).

The School of American Archaeology conducted many field schools at BNM. However, no major reports resulted from these excavations (Mathien et al. 1993 and Powers and Orcutt 1988). In 1935, the National Park Service (NPS) (which controlled the land on the Pajarito Plateau outside the BNM) produced a map of 200 sites on the Ramon Vigil Grant. Other material from the survey has been lost (Mathien et al. 1993).

Archaeological investigations on the Pajarito Plateau continued after World War II at BNM (Powers 1988, Caywood 1966, and Powers and Orcutt 1988), on the Los Alamos Scientific Laboratory (LASL) (Steen 1982, Worman 1967, and Worman and Steen 1978), and on privatized land in what is now the city of Los Alamos and the community of White Rock (Maxon 1969, Hill and Trierweiler 1986, and Kohler 1989). LASL hired archaeologist F.V. Worman in 1950, and since then, regular archaeological surveys and excavations have been made prior to all construction at LASL/LANL (Mathien et al. 1993, LANL 1986–1995, Steen 1982).

LASL and LANL archaeologists have conducted hundreds of site excavations and surveys and have compiled and published numerous documents over the past 47 years. Although approximately 75 percent of LANL has been archaeologically surveyed (LANL 1995c), the number of cultural resources at LANL, the complexity of their cultural affiliations and types, and the manner in which they have been studied and recorded make systematic classification difficult. A cultural resources bibliography has been compiled for the Pajarito Plateau (Mathien et al. 1993). In addition, the resource records have been included in a relational database and many resurveys and refinements have been made to the original field data (PC 1996).

E.2.2 Studies of Historic Resources at LANL

Increased interest in the documentation and preservation of Nuclear Energy Period resources has come about since the end of the Cold War and publishing of the National Register of Historic Places (NRHP) guidance on the eligibility of resources less than 50 years old (U.S. Department of Defense [DOD] 1993 and NPS 1990). Citizens of Los Alamos County have supported historic preservation efforts that have focused on the legacy of the Manhattan Project. Survey work conducted in December of 1966 and 1968 resulted in the nomination for listing on the NRHP of the Los Alamos Historic District, including Ashley Pond, Fuller Lodge, Central Avenue LANL Administration Building, Los Alamos County Historical Museum and Archives, and other Manhattan Project properties outside the boundaries of LANL (NMHPD 1995).

While the potential significance of LANL as a site of outstanding importance in the development of nuclear energy is recognized by DOE, the State Historic Preservation Office(r) (SHPO), and the LANL Cultural Resources Management Team, comprehensive surveys have yet to be conducted for Nuclear Energy Period resources at LANL. A survey of 28 Cold War Period resources was conducted in 1995 by the LANL Cultural Resources Management Team prior to decontamination and decommissioning of buildings on the S-Site (TA–16), a critical area of high-explosive atomic research activity for the Manhattan Project. The results of this survey have been published as an Historic Building Survey Report (McGehee 1995). In the report, all 28 buildings were recommended as eligible for listing in the NRHP because of primary or secondary contributions to events of exceptional international importance. These buildings were also identified as contributing properties to a potential World War II and Cold War historic district at TA–16. According to McGehee, “A formal evaluation of the proposed district will be included in an overall evaluation and management document currently being drafted for all historic properties at LANL” (McGehee 1995).

E.2.3 Studies of Traditional Cultural Properties

Previously conducted TCP studies, identified during the course of this study, are summarized below. One problem encountered in compiling this review was a lack of comprehensive files available to researchers conducting ethnographic research in New Mexico. There is no central facility for ethnographic reports or lists of TCP sites.

In the past 5 years, as laws have changed to include protection of traditional places, several studies of TCPs have been conducted in central and northern New Mexico. In 1992, the Fence Lake Ethnographic Study was completed for the Salt River Project's proposed Fence Lake Mine in western New Mexico (Hart and Ferguson 1993). The Pueblos of Zuni and Acoma, the Hopi Tribe, and the Ramah Band of the Navajo Nation participated in this study. Information was collected through a literature study, meetings, and field work with the consulting tribes to document tribal use of the area as well as concerns revolving around proposed development. Several cultural resources significant to the consulting tribes were documented in or adjacent to the LANL region. These resources include the Zuni Salt Lake, the Zuni Salt Lake Neutral Zone, seven historic American Indian trails, numerous sacred places, ancestral homesites, ancestral graves and collection areas, prehistoric Pueblo ruins, and Cerro Prieto, a black volcanic cone. With the exception of the ancestral graves, most of these sites were recommended as eligible as a TCP for inclusion in the NRHP (Hart and Ferguson 1993).

A rapid ethnographic assessment of the Petroglyph National Monument was conducted in 1991 to 1992 to identify those American Indian tribes and Spanish heritage groups who were interested in participating in a long-term consultation process with the NPS concerning the management of the PNM (Evans et al. 1993). Once the groups were identified, cultural resource concerns were identified through letters and meetings with various tribal and Hispanic groups. Although specific cultural resource information was not made public, the consulting parties set forth several recommendations pertaining to management of the Petroglyph National Monument (Evans et al. 1993).

The Office of Contract Archeology at the University of New Mexico completed an ethnographic study of the Fort Wingate Depot Activity in 1994, as part of the closure process of the facility by the U.S. Army (Perlman 1995). The purpose of the study was to conduct a sample survey and an initial TCP assessment of sites located on the base that are of significance to the Navajo and Zuni people. This study was accomplished through a series of meetings and field work with the Church Rock, Iyanbito, and Bread Springs Chapters of the Navajo Nation and the Zuni Heritage and Historic Preservation Office. Through this TCP study and previous investigations, 24 cultural sites were identified, 15 of which were recommended for nomination to the NRHP as TCPs. Eight burials sites were identified and recommended as eligible for protection under the *Native American Graves Protection and Repatriation Act* (NAGPRA) (25 U.S.C. §3001).

American Indian concerns regarding traditional places in the Paseo del Volcan transportation corridor were documented in a study done in 1993 and 1994 as part of a project sponsored by the Federal Highway Administration and the New Mexico State Highway and Transportation Department (SWCA 1995). The purpose of the project was to identify a corridor that could be used to serve future transportation needs in the Albuquerque area. Nineteen New Mexico Pueblos, the Canoncito Navajo Chapter, the Hopi Tribe, and the Jicarilla and Mescalero Apache Tribes were initially contacted. Of this original group, ten expressed concerns about the project. Through a series of letters, meetings, and field work with these groups, concerns were identified regarding traditional use of the project area. This was only a preliminary study, and no TCPs were identified by the consulting tribes. It became apparent during the study that unless a specific corridor was selected from the alternatives, the tribal consultants would not identify specific places of concerns (SWCA 1995). The Paseo del Volcan corridor study also identified three Hispanic TCPs in the Bernalillo area, including a historic neighborhood, the location of a religious fiesta that includes Matachines dances, and a pilgrimage route (SWCA 1996a).

Three TCP studies have been completed for the U.S. Bureau of Reclamation (Reclamation). In 1995, an initial TCP study was completed of Heron and El Vado Reservoirs in Rio Arriba County (SWCA 1996b). Initial contact letters were mailed to 11 tribes and 3 parish priests in the Chama area. In response to these letters, meetings were held with two of the tribes and one parish priest. The priest also participated in a field visit to the reservoirs. In response to these letters, meetings, and field visit, four Pueblos, the Jicarilla Apache Tribe, and Hispanic communities were identified as having concerns about the protection of potential cultural resources in the area of the two reservoirs (SWCA 1996a). As funding becomes available, a more intensive TCP study will be done for these two reservoirs.

In early 1996, an initial TCP study was completed at the White Ranch Property in Saguache County, in southern Colorado (SWCA 1996c). Contact was initiated with ten tribes in an effort to determine if these groups had concerns regarding the transfer of the White Ranch parcel from Reclamation to the U.S. Department of the Interior (DOI), U.S. Fish and Wildlife Service (FWS). Through this initial consultation, which included letters and meetings, five tribes indicated that they had concerns regarding cultural resources on the parcel. Two tribes requested field visits to the study area. As a result of this initial study, several recommendations were made, mainly in the form of further consultation and field visits with consulting tribes. Because this parcel is scheduled to be transferred to the FWS, it is anticipated that additional TCP investigations will be conducted (SWCA 1996c).

From 1992 through 1995, one of the more extensive TCP studies was conducted of the Animas-La Plata Project in southwestern Colorado and northwestern New Mexico (NAU and SWCA 1996). At the conclusion, 26 American Indian tribes had become involved in a complex consultation process involving contacts by letters, telephone calls, meetings, and field work. An extensive literature review also provided valuable information to the study. Through this study, TCPs and sacred places were identified, an assessment of the project impacts on these properties and places was made, and management recommendations were provided. The potential TCPs identified in the project area were a prehistoric/historic trail, puebloan habitation and ceremonial archaeological sites, and a traditional collections area (NAU and SWCA 1996).

In July 1995, an initial TCP study was conducted of the Westland Sector Plan Property in Bernalillo County (SWCA 1996d). The client and the city of Albuquerque Planning Department identified the groups to be contacted. These groups included one Pueblo, heirs and stockholders in the Westland Development Company, and two Hispanic community organizations. Consultation took the form of contact through letters, meetings, and interviews. The results of the literature review indicated the presence of various cultural resources on the West Mesa, with the heaviest incidence of use being within the boundaries of the Petroglyph National Monument. With the exception of one land rights organization, these groups did not have concerns regarding cultural resources located within the sector.

E.3 CULTURAL BACKGROUND OF THE LANL REGION

The following subsections contain a history and summaries of previous studies of the cultural background in the LANL region.

E.3.1 Prehistoric Background of the LANL Region

Previous archaeological investigations in the vicinity of the Pajarito Plateau indicate that the area has a history dating back many thousands of years. Researchers have developed socio-historical schemes to describe the cultural periods of the region (Kidder 1927). In 1954, Fred Wendorf defined five major periods for the northern Rio Grande Valley: Preceramic, Developmental, Coalition, Classic, and Historic (Wendorf 1954). These period classifications, with some modifications, are still in use (Pratt and Scurlock 1993). The Preceramic Period has been divided into Paleo-Indian and Archaic, based upon changes in settlement patterns and subsistence over time as reflected by material culture. The Historic Period includes both American Indian sites, where people abandoned their homelands and changed their ways of life in response to Euro-American and other influences, and sites that reflect the European and American settlement of the Rio Grande Valley. A summary of these periods is presented in Table E.3.1–1. Brief discussions of the highlights of each period follow.

E.3.1.1 *Paleo-Indian Period (10,000 Through 4000 B.C.)*

By the end of the Wisconsin glacial stage, 10,000 years ago, the entire area of the North American continent, including New Mexico, was occupied by people whose subsistence was based on hunting and gathering (Willey 1966). Archaeological sites dating from this period contain bones of mammoths and bison and distinctive lanceolate projectile points, in association with a variety of stone butchering tools and lithic debitage. Paleo-Indian artifacts made of obsidian from the Jemez Mountains have been found in other parts of the Southwest (Broster 1983). Obsidian deposits were exposed in ancient landslides at higher elevations and around the margins of Valle Grande to the northwest (Powers 1988). Sites of the Paleo-Indian Period may be found in any part of LANL; however, no discoveries of Paleo-Indian remains have been made (Wolfman 1994 and LANL 1995c). Paleo-Indian materials have been reported near Cochiti; however, these were confined to surface finds of projectile points and lithic debitage (Biella 1977, Biella and Chapman 1977–1979). Because any information concerning the Paleo-Indian Period would contribute to the development of the historical context, all sites of this period are likely to be significant.

E.3.1.2 *Archaic Period (4000 B.C. Through A.D. 600)*

American Indians altered their lifestyles in response to a continuing shift of the climate toward present-day conditions at the end of the Pleistocene Period. By this period, the big game of the Pleistocene era had died out and a heavier reliance was placed on hunting and gathering. Although bison hunting continued to be important (Stuart and Gauthier 1981), small game such as deer, raccoon, turkey, and squirrel became an increasingly significant component of the diet (Larson 1991). Group movements became tied to the seasonal availability of plants. This change in subsistence was accompanied by a change in the tool assemblage, with broad-stemmed projectile points, stone knives, fish hooks, jewelry, and grinding stones becoming common. Archaic Period sites include cave and rock shelter sites, burned rock features, scatters of tools and lithic debitage, and isolated hearths. On the Pajarito Plateau, Archaic Period sites are most likely to

TABLE E.3.1–1.—*Archaeological Periods of Northern New Mexico*

TIME PERIOD	PREHISTORIC PERIOD	CHARACTERISTIC SITE TYPES
10,000 through 4000 B.C.	Paleo-Indian	• Bones of mammoth or bison • Stone butchering tools • Flakes and chips of stones from making stone tools • Distinctive lance-shaped projective points
4000 B.C. through A.D. 600	Archaic	• Caves and rock shelters • Burned rock features • Scatters of tools and stone flakes and chips • Isolated hearths • End of the Archaic period (approximately A.D. 1 to 700) may have pottery grinding stones, and charred corn
A.D. 600 through 1100	Developmental	• Ceramic storage and service vessels • Smaller projectile points reflecting the adoption of the bow and arrow • Grinding tools • Dwellings increased in size and complexity from semisubterranean pithouses to small adobe or crude masonry structures
A.D. 1100 through 1325	Coalition	• Early sites are rectangular structures of adobe and masonry with basin-shaped, abobe-lines fire pits, usually in the center of the room or against a wall • Comparatively small; pueblos average 28 rooms • Later coalition sites contain plazas and room blocks of more than 100 rooms
A.D. 1325 through 1600	Classic	• Large masonry structures of multiple-room blocks • For the Pajarito Plateau, three site clusters, one of which includes Navawi, Otowi, Tsankawi, and Tsirege • Associated one- to two-room isolated structures

Sources: Cordell 1979, Cordell 1984, LANL 1995c, Stuart and Gautheir 1981, Wendorf 1954, and Wolfman 1994.

be represented by concentrations of lithic debitage.

E.3.1.3 *Developmental Period (A.D. 600 Through 1100)*

About A.D. 600, the prehistoric occupants shifted their subsistence and settlement patterns toward a more sedentary lifestyle and intensified horticultural practices (Powers 1988), including the cultivation of maize, beans, and squash. In the LANL region, the Developmental Period has been subdivided into early and late phases (Wolfman 1994). These subdivisions appear to reflect observable trends in increased sedentary behavior and social complexity. Additional attributes of the Developmental Period include the advent of ceramic storage and service vessels, smaller projectile points, the adoption of the bow and arrow, continued use of grinding tools, and increases in size and complexity of houses. During the Early Developmental Period (A.D. 600 through 900), single family units were built in semi-subterranean pit houses. Late Developmental Period sites (A.D. 900 through 1099) were typically small adobe or crude masonry structures. Although they are scarce on the Pajarito Plateau (Wolfman 1994), sites attributable to the Developmental Period have been identified at LANL.

E.3.1.4 *Coalition Period (A.D. 1100 Through 1325)*

During the Coalition Period, the local populations coalesced into larger societal units. Subsistence was based on maize horticulture. The early sites are rectangular structures of adobe and masonry. Basin-shaped, adobe-lined fire pits are usually in the centers of the rooms, or sometimes against a wall. Circular or D-shaped semi-subterranean kivas are often in front of the room blocks (Larson 1991). Fairly small Pueblos, averaging 28 rooms, were typical of the Coalition Period (Wolfman 1994), although late Coalition Period sites are large masonry structures exhibiting plazas and room blocks of over 100 rooms (LANL 1995c). Over 700 Coalition Period ruins have been found within LANL boundaries.

E.3.1.5 *Classic Period (A.D. 1325 Through 1600)*

During the Classic Period, maize-based horticulture intensified and settlements on the Pajarito Plateau further coalesced into three main population centers. One of these site clusters consists of four sites that temporally overlapped: Navawi, Otowi, Tsankawi, and Tsirege (LANL 1995c). These sites are large masonry structures of multiple room blocks, with associated one- or two-room isolated structures. Otowi and Tsirege appear to be the ancestral sites of the Pueblo of San Ildefonso. Severe droughts in the 1500's led to abandonment of many of the Pueblos and the Pajarito Plateau. The scarcity of water and crop failures probably forced gradual relocations to more reliable water sources in the Rio Grande Valley (Sando 1992). Tree-ring dating (dendrochronology) from the Frijoles Canyon Pueblos indicates that the last roof beams were cut around 1550 (Robinson et al. 1972). The exodus probably took place over many years. At the time of the Spanish arrival in 1597, most activity had ended on the Pajarito Plateau and four Pueblos were established in the adjoining Rio Grande Valley: the Pueblos of Santa Clara, Jemez, San Ildefonso, and Cochiti.

E.3.2 Historic Background of the LANL Region

This subsection presents highlights of historic events that occurred in the LANL region.

E.3.2.1 *Spanish Colonial Period (A.D. 1600 Through 1849)*

The inhabitants of the Rio Grande Pueblos still remember their ancestral homes on the Pajarito Plateau at the time of the Spanish Conquest (Hewett and Dutton 1945). There is archaeological evidence that the abandoned canyons with their Pueblos and caves were visited for ceremonial purposes. Pictographs of horse figures exist in some kiva ruins at BNM and on canyon walls in White Rock Canyon (Kessell 1979). These may indicate that the area was occupied by a small remnant population after the Spanish occupation of the Rio Grande Valley. Game pits on the Pajarito Plateau could also date from the time of the Spanish occupation or later. The use of the area from that time forward seems to have been for occasional hunting and gathering or ceremonial use, including burials (Steen 1977). American Indian sites relating to this early Historic Period are classified as historic sites.

The Coronado expedition entered the region of the Rio Grande Pueblos in 1540. Hernando de Alvarado and his commander, Francisco Coronado, waged intermittent battles with individual Pueblos for food and supplies (Kessell 1979). The Spanish did not meet with much success in New Mexico and retreated to Mexico in April 1542 (Jenkins and Schroeder

1974). The 1598 expedition by Juan de Oñate arrived in Northern New Mexico with strong military backing, livestock, and equipment for full colonization. The Pueblos of the Rio Grande Valley continued to shrink in size during this 50-year interlude, and some locations inhabited when Coronado first entered the Valley were no longer occupied when Oñate arrived (Schroeder 1979). Pueblo leaders voluntarily took oaths of allegiance to the Spanish Crown and accepted the Franciscans who took up residence in each Pueblo. Churches were added to each Pueblo early in the seventeenth century (Simmons 1979a).

In 1610, the Spanish capital of New Mexico was relocated to Santa Fe by Governor Pedro de Peralta (Kessell 1979). The extensive Palace of the Governors was built to serve the administration of New Mexico as the settlement of the area continued (Kessell 1979). This Spanish Colonial Period was not peaceful, and the Pueblos were beset by incursions from the Spanish settlers, epidemics of smallpox and other deadly diseases, and continual attacks by Apaches (Simmons 1979a). In 1680, the Pueblos openly revolted against Spanish rule, attacking the Spanish settlers and Franciscans in the Rio Grande Valley and laying siege to the Palace of the Governors in Santa Fe. The Spanish Governor, Otermin, and most other Spanish settlers were forced south to El Paso (Hendricks 1993). American Indian governors ruled New Mexico from the Palace of the Governors for 12 years, until 1693 when Spanish control was reestablished. In 1821, the Spanish population in New Mexico had reached 20,000 to 25,000 (Simmons 1979b).

In the late seventeenth century, the Spanish Crown provided land grants adjoining the Pajarito Plateau to four Pueblos in New Mexico (Brayer 1938). The Jemez Pueblo was originally granted 17,331 acres (7,014 hectares) in 1689. Pueblo de Cochiti was granted over 20,000 acres (8,094 hectares); Santa Clara Pueblo was granted 44,818 acres (18,138 hectares); and San Ildefonso Pueblo was granted 15,413 acres (6,237 hectares) during this period (Simmons 1979a). American Indian populations continued to decline from disease during the Spanish occupation. The Pueblos surrounding the Pajarito Plateau suffered tremendous population losses. According to published records of the Spanish census of New Mexico, population totals fell from a combined 6,400 in Jemez, San Ildefonso, Santo Domingo, Santa Clara, and Cochiti Pueblos in 1630 to 1,374 in 1821 (Simmons 1979b).

Mexico was granted independence from Spain with the signing of the Treaty of Córdova in 1821. The treaty granted full Mexican citizenship to all American Indians (Kessell 1979). The quarter-century of Mexican administration in New Mexico was not marked by any major changes in the legal or cultural affairs of the state. However, it did open up major new trade routes and commerce between Santa Fe and the U.S. By 1824, New Mexicans were, for the first time, buying more from U.S. merchants than from their traditional Chihuahuan sources, and the Santa Fe Trail became important for U.S. traders selling goods to Mexico (Jenkins and Schroeder 1974).

Use of the Pajarito Plateau during the Spanish Colonial and Territorial Periods is not well documented (LANL 1995c). Grazing, seasonal gathering of firewood and timber, and hunting were probably practiced by the growing Hispanic population and by the nearby American Indian communities.

E.3.2.2 *Early U.S. Territorial/ Statehood Period (A.D. 1849 Through 1942)*

U.S. Army General Stephen Watts Kearny occupied New Mexico when the Mexican War broke out in 1846. The Pueblos of the Rio Grande Valley and the rural Spanish culture of northern New Mexico had become accustomed to changing political authority in Santa Fe and generally did not resist the change in power. However, in 1847, a rebellion broke out at Taos Pueblo. The brief revolt was bloody and rapidly put down by the U.S. Army (Jenkins and Schroeder 1974). The Treaty of Guadalupe-Hidalgo (1849) formally ended the question of authority in New Mexico and the new administration soon took effect. U.S. policy toward American Indians, including lands and citizenship, was very different from that of Spanish or Mexican administrators. The cornerstones of U.S. American Indian relations were isolation of tribes into separate reservation lands and provision of military protection and education. The first American Indian agent was assigned to New Mexico in 1849, as part of the territorial administration. In the shaping of the first steps toward statehood, the original Spanish and Mexican land grants in New Mexico were formally recognized (Leonard 1970 and Carlson 1990).

The early U.S. homesteaders may have informally begun using the Pajarito Plateau shortly after the U.S. Territory was established by the *Homestead Act of 1862*, which officially opened any untitled lands in New Mexico to settlement. By 1890, the Pajarito Plateau was still only sparsely settled by Hispanic and Anglo homestead ranches (Seidel 1995). The remains of these homesteads usually consist of wooden cabins, corrals, rock and cement cisterns, and agricultural debris such as barbed wire, wagon parts, horseshoes, and other evidence of livestock raising and transportation methods.

Since 1900, the remote and scenic location of the Pajarito Plateau has attracted outdoorsmen for hunting and fishing. The Jemez Mountains and antiquities of the Pajarito Plateau brought many visitors to the area once BNM was established in 1916 (Seidel 1995). The present site of Los Alamos was purchased in 1917 by Ashley Pond. In 1918, Pond established the Los Alamos Ranch School, a private boys' school. The school specialized in residential secondary education and attracted many young men from wealthy eastern families seeking robust physical development as well as academic education (Seidel 1995). The main recreation lodge and dining hall of the school, Fuller Lodge, is now part of a National Historic District and is a registered national historic landmark. The lodge, built in 1928, is constructed of logs and was designed by John Gaw Meem. The school operated from 1918 until 1943, when the facilities were acquired by the U.S. government for the Manhattan Project (Seidel 1995).

E.3.2.3 *Nuclear Energy Period (A.D. 1943 to Present)*

Because of very well-defined changes in the function of LASL/LANL, the Nuclear Energy Period is further broken into three periods: World War II/Early Nuclear Weapon Development, Early Cold War, and Late Cold War.

World War II/Early Nuclear Weapon Development Period (A.D. 1943 Through 1948)

The latest era in the historic development of the LANL region began in 1943 with the purchase of the Los Alamos Ranch School by the Secretary of War, as part of the wartime effort to build a secret nuclear weapons program (Seidel 1995). LASL was involved from the very inception of the U.S. government's program to develop nuclear weapons for the war effort (Truslow 1991). LASL was not only representative of wartime research and development facilities, but it provided innovative scientific and technological research and development activities for the U.S. nuclear weapons program from 1943 until the end of the Cold War in 1989. Los Alamos was the original site selected for the design and construction of the first nuclear bomb because of its remote and secret location (Truslow 1991).

The Los Alamos Early Nuclear Weapon Development Period facilities at LASL were built and used in the creation of the first atomic bomb, which was detonated successfully in July 1945. The design and manufacture of the Trinity bomb; the Hiroshima bomb, Little Boy; and the Nagasaki bomb, Fat Man; took place at LASL (Truslow 1991). LASL and the Trinity Test Site near Alamogordo, New Mexico, represent World War II nuclear weapon development events of exceptional importance on an international scale.

World War II research and development activities were concentrated around the Los Alamos Boys Ranch School, which became the living center for scientists during the war. Laboratories were erected at more remote locations. The S-Site, for example, was developed for high explosives research (Truslow 1991). This set a pattern for later development at LASL, where housing and administration remained concentrated around the present Los Alamos townsite and the former site of the Los Alamos Boys Ranch School. A back gate was erected to control access to the remote laboratories of the S- and V-Sites (Truslow 1991). From 1946 through 1950, all nuclear weapons were made at Los Alamos (DOE 1995). Common remains from this period and the following Early Cold War Period consist of laboratory and administration buildings, security facilities, experimental areas, infrastructure support facilities, berms and barricades, and paved and unpaved roads.

Early Cold War Period (A.D. 1949 Through 1956)

The mission of nuclear weapons development did not end with the close of World War II. In 1946, the Atomic Energy Commission (AEC) became the administrator of LASL, and nuclear weapons research and development continued (Seidel 1995). The Early Cold War Period began when the Union of Soviet Socialist Republics (U.S.S.R.) exploded its first atomic bomb in 1949 and the U.S. government became dedicated to nuclear weapons development and production in a nuclear arms race (LaFeber 1993). The Early Cold War Period was characterized by international tensions, armament buildup, and mostly military conflict by proxy waged in remote areas of the developing world.

LASL was the first, and later, one of only 13 sites in the U.S. devoted to nuclear weapons development and production (Seidel 1995). During the Early Cold War, LASL became a primary research and development center for U.S. nuclear programs, while production was shifted to other facilities. The period from 1949 to 1956 brought a considerable amount of new construction to LASL to meet the research needs of rapid nuclear armament buildup and international tensions between the U.S. and the U.S.S.R.

From 1943 until 1957, the entire Pajarito Plateau was shielded from public access. Los Alamos was closed and the mission and activities at LASL were classified (Seidel 1995). The city had grown to approximately 5,000 scientists and their families by 1945. In 1941, Los Alamos County was partitioned from Sandoval County and Santa Fe County, with the AEC controlling nearly all acreage in the new county (Seidel 1995).

Late Cold War Period (A.D. 1957 Through 1989)

In 1957, parts of the Pajarito Plateau, including the Los Alamos townsite, were opened to the public, marking the beginning of the Late Cold War (Seidel 1995). Throughout the Cold War, the LASL mission continued to be one of innovation and the scientific development of more powerful and efficient nuclear weapons and delivery systems. The Late Cold War was marked by more diversified research goals. Several periods of construction have occurred at LASL since 1956, but have yet to be analyzed. In 1977, the present boundaries were established, the name was changed to LANL (Steen 1977), and management of LANL was awarded to the University of California (UC) (Seidel 1995).

The international events that may be reflected in the physical record at LANL during this period include (DOD 1993):

- *1957*. First underground nuclear test, first intercontinental ballistic missile (ICBM) developed, first successful test of Atlas missiles.
- *1958*. First Nike-Hercules missile.
- *1961*. U.S. resumes underground testing of nuclear weapons; U.S.S.R. resumes atmospheric testing.
- *1962*. East-West conference on banning nuclear weapons tests takes place; U.S. resumes atmospheric testing of nuclear weapons.
- *1967*. Treaty of Tlatelcoco prohibits introduction and manufacture of nuclear weapons in Latin America (signed by all Latin American countries except Cuba).
- *1968*. Nuclear Arms Non-proliferation Treaty signed by U.S., U.S.S.R., and 58 other nations.
- *1970*. Nuclear Arms Non-proliferation Treaty goes into effect.
- *1976*. U.S. and U.S.S.R. sign peaceful nuclear explosions treaty limiting testing.
- *1979*. North Atlantic Treaty Organization (NATO) announces "dual-track" intermediate-range nuclear forces to intercept Warsaw Pact SS-20 missiles.
- *1983*. Congress authorizes MX missile procurement and development; Scowcroft Commission calls for modernizing U.S. strategic weapons.
- *1985*. Nuclear and space talks open in Geneva.
- *1986*. Peacekeeper ICBM becomes operational.
- *1987*. U.S. and U.S.S.R. sign Nuclear Risk Reduction Agreement, eliminating intermediate range nuclear weapons.
- *1989*. Fall of the Berlin Wall.
- *1991*. Presidents Bush and Gorbachev sign Strategic Arms Reduction Treaty (START); dissolution of the Warsaw Pact.

LANL's nuclear mission continued to be the primary focus of Los Alamos County until the end of the Cold War in 1989, creating a uniquely specialized scientific community in this remote region of New Mexico. The fall of the Berlin Wall in 1989 and the dissolution of the Warsaw Pact in 1991 effectively ended the international tensions that drove the nuclear development mission at LANL (DOD 1993).

E.3.3 Traditional Cultural Background in the LANL Region

A TCP is a significant place or object associated with historical and cultural practices or beliefs of a living community that is rooted in that community's history and is important in maintaining the continuing cultural identity of the community (Parker and King 1990). TCPs are essential in preserving cultural identity through social, spiritual, political, and economic uses. Federal guidelines established by the NPS (Parker and King 1990) identify TCPs to include

- Natural resources.
- Prehistoric and historic archaeological sites.
- Traditional use areas in the cultural landscape that do not reveal evidence of human use.
- Rural communities whose organization, buildings and structures, or patterns of land use reflect the cultural traditions valued by its long-term residents.
- An urban neighborhood that is the traditional home of a particular cultural group and that reflects its beliefs and practices.
- A location where a community has traditionally carried out economic, artistic, or other cultural practices important in maintaining its historical identity.

For TCPs on other lands, tribal rights have been established in the federal decision-making process. SWEIS consultations have been conducted in accordance with applicable federal requirements to include NHPA (16 U.S.C. §470), NAGPRA, *American Indian Religious Freedom Act* (AIRFA) (42 U.S.C. §1996; EO 13007), and DOE and LANL Accord Agreements with the Pueblo de Cochiti and the Pueblos of Jemez, Santa Clara, and San Ildefonso (DOE et al. 1992).

TCPs are not limited to ethnic minority groups, and traditional cultural contexts of northern New Mexico include cultural groups other than American Indians. Americans of every ethnic origin have properties to which they ascribe traditional cultural value. The Hispanic culture, in particular, has maintained traditional communities, practices, beliefs, and subsistence patterns in northern New Mexico.

E.3.3.1 *American Indian Cultures in the LANL Region*

The diversity of American Indian traditional cultural practices in the Southwest is reflected in the number of languages and complex cultures that occur there. Language is essential to the preservation of these cultural practices.

There are five different language families in the LANL region: Tanoan, Keres, Zuni, Uto-Aztecan, and Athabaskan (Hale and Harris 1979). These languages are presented in Table E.3.3.1–1 to show the relationships among the American Indian communities that speak each of the languages. The diversity of the languages also illustrates the complexity of multicultural relations in the region.

Every recognized American Indian community is a sovereign nation with limited powers. In accordance with the DOE American Indian

TABLE E.3.3.1–1.—*Languages of American Indian Communities within the LANL Region*

LANGUAGE FAMILY	SUBFAMILIES	COMMUNITIES THAT SPEAK THE LANGUAGE	
Tanoan	Tiwa (Northern and Southern dialects)	Pueblo of Taos Pueblo of Picuris	Pueblo of Sandia Pueblo of Isleta
	Tewa	Pueblo of San Juan Pueblo of Santa Clara Pueblo of San Ildefonso	Pueblo of Pojoaque Pueblo of Nambe Pueblo of Tesuque Arizona-Tewa
	Towa	Pueblo of Jemez	
Keres	(Eastern and Western dialects)	Pueblo de Cochiti Pueblo of Santo Domingo	Pueblo of Santa Ana Pueblo of San Felipe Pueblo of Zia
Zuni		Pueblo of Zuni	
Uto-Aztecan	Shoshonean	Hopi Tribe (Several villages on the First, Second, and Third Mesas, Arizona)	
Southern Athabascan	Eastern Apache	Jicarilla Apache Tribe	Mescalero Apache Tribe
	Western Apache	Navajo Nation (Navajo language)	

Source: Hale and Harris 1979.

Policy, DOE interacts with federally recognized tribes on a government-to-government basis (DOE 1994). In 1992, DOE and the Pueblos of San Ildefonso, Santa Clara, Cochiti, and Jemez, which are located near or directly adjacent to LANL, entered into formal agreements called Accords. The purpose of the Accords was to improve communication and cooperation among federal and tribal governments. In 1994 and in 1996, the Pueblos of San Ildefonso, Cochiti, Jemez, and Santa Clara also signed cooperative agreements with DOE and UC to promote a meaningful participation and consultation on Pueblo environment, safety, health, and religious-culturally significant matters. The Accords and cooperative agreements are discussed further in chapter 7, section 7.2.9.

In Apache and Navajo communities (Athabascan cultures), tribal governments are based on the electoral process. Tribal members select a president and vice president during the summer for a 4-year term of office. The Navajo Nation has 110 political subdivisions, called "Chapter Houses" (e.g., Alamo, Cañoncito), that are represented in the Council. Initially, federal agencies must consult with the President of the Navajo Nation directly, but later requests may be referred to specific tribal departments or chapters.

The role of tribal governments is to interact with outside organizations such as county, state, and federal bureaucracies on a variety of issues. These issues include casinos and economic development, litigation, tribal court systems, land claims, hazardous waste transportation through tribal lands, construction projects compliance with tribal environmental standards, Indian health clinics, grave repatriation issues, language preservation programs, and cultural resources management.

E.3.3.2 *Traditional Hispanic Communities in the LANL Region*

LANL is located near numerous traditional Hispanic communities in four counties: Santa Fe, Sandoval, Rio Arriba, and Taos. While many of the cultural characteristics and demographics of the larger towns and cities of northern New Mexico have changed in recent years, many small, rural, and primarily Spanish-speaking communities, identified as traditional communities, continue to exist. Many communities were first settled during the Spanish Colonial Period and were given their land by the Spanish Crown (Weigle 1978). The identity of traditional Hispanic communities is maintained partly through archaic linguistic patterns and vocabulary carried over from early Spanish colonization of the area and partly through the traditional beliefs and practices unique to the region. Traditional Hispanic communities in northern New Mexico also maintain religious practices, art and craft traditions, folklore, and traditional medical practices (Ahlborn 1968, Briggs 1980, Weigle 1978, and Carlson 1990).

A traditional element present in these communities is the use of shared community ditches, or acequias, for irrigation (Carlson 1990). For that reason, these communities are sometimes known as acequia communities. (Campa 1979). Acequias are not only ditches but also traditional cultural systems that organize allocating, distributing, and sharing water in an arid land. Acequia systems are governed by traditional practices that are derived from Spanish Colonial laws of the seventeenth and eighteenth centuries (Weigle 1978 and Carlson 1990). The social labor systems necessary to operate the ditches include commissioners (elected representatives), mayordomos/mayordomas (ditch managers), and parcipiantes (landowners/shareholders) (Meyer 1984). Acequias are also political subdivisions of the State of New Mexico, recognized for their role in the development and administration of water resources for irrigation. The acequia system in the region is also closely intertwined with the Catholic Church.

E.3.3.3 *Traditional Cultural Property Categories*

Because of the numerous traditional cultures present in the region, the discussion of TCPs will be based on resource categories as well as the particular cultural affiliation of the community. The traditional cultures of the region have had many generations of interaction with one another and often have overlapping subsistence, artistic, and religious practices with unique cultural importance attached to similar types of sites. Several general categories of TCPs have been identified in the literature on American Indian and Hispanic cultures in northern New Mexico. Each of these categories represents specific cultural and physical sensitivity and susceptibility to adverse impacts from LANL operations. TCP resource types or categories in northern New Mexico include:

- Ceremonial and archaeological sites
- Natural features mentioned in stories, myths, and legends
- Ethnobotanical plant-gathering sites
- Artisan material-gathering sites
- Places used in traditional subsistence activities

These resource types are described in the following subsections, providing an overview of the range and diversity of potential TCPs in northern New Mexico.

Ceremonial and Archaeological Sites

Religious and ceremonial sites may be TCPs if they are still a part of the living memory and practices of traditional communities. Both American Indian and Hispanic communities have many ceremonial sites in northern New Mexico, including American Indian shrines and places of ceremony, Hispanic shrines, sanctuaries and meeting houses of the Catholic lay-brotherhood, known as Los Hermanos Penitentes.

American Indian groups visit and use a variety of ceremonial sites and shrines that are part of the landscape. The locations of tribal ceremonial sites and shrines are often held in secret by religious societies in the Pueblos (Starr 1900). Some American Indian ceremonial sites are marked with stones or other man-made features, while others are preserved in the living memory of the societies that visit them (Harrington 1916 and Douglas 1917). Some sites are visited only on rare occasions as particular circumstances demand it (Lange 1959 and Nordhaus 1995). The locations of some shrines have been previously published, but in the interest of preserving the privacy of the tribes, only general locations have been indicated throughout this technical report.

Most American Indian ceremonial sites remain unrecorded. Examples of recorded American Indian ceremonial sites within or near LANL boundaries include shrines that are known to exist around Mount Pelado, Redondo Peak (Akins 1993 and Ellis 1979); around Ovahwi Peak, Capulin Canyon, and Black Mesa (Akins 1993, Harrington 1916, and Douglas 1917); and along the Rio Grande, Tsikomo Peak, Nipple Mountain, Potrero de los Idolos, Peña Blanca, and Canada de Peralta. Shrines are also recorded for several caves in the area (Akins 1993, Harrington 1916, and Lange 1959).

Sanctuaries, shrines, and religious structures dating from the Colonial Period in New Mexico, are still widely revered and used by traditional communities, both Hispanic and American Indian. These sanctuaries may be completely ruined at this time or may have been extensively restored. The Santuario de Chimayo is widely visited by pilgrims from traditional Hispanic villages around New Mexico (Treib 1993). Sanctuaries at Cochiti, Santa Domingo, San Felipe, Zia, and Picuris Pueblos are enduring locations of traditional ceremonial practice (Treib 1993). The Oratorio of San Ysidro, the sanctuary of San Vicente De Paul in Punta de Agua, the church of San Miguel in La Bajada, and the church of San Jose de Gracia de Las Trampas are other examples of important Hispanic sanctuaries (Treib 1993). The ruins of San Jose de Giusewa in Jemez Springs are no longer in use as a sanctuary, but remain part of the continuing Catholic traditions of the Jemez Valley.

Moradas are ceremonial features unique to the Spanish traditions of northern New Mexico (Ahlborn 1968 and Wallis 1994). These structures serve as chapter houses for the lay-brotherhood of La Fraternidad Piadosa de Nuestro Padre Jesus Nazareno, also known as Los Hermanos Penitentes (Wallis 1994). Los Hermanos Penitentes originated in Spanish Colonial New Mexico and were formally organized between 1776 and 1833 during a period when there were insufficient priests to serve the needs of the Hispanic communities. The village moradas still serve to bring the traditional Hispanic community together and preserve teaching and values unique to the region through their community meetings, teachings, and ceremonies (Ahlborn 1968 and Wallis 1994).

Community members who move away for work often return for annual ceremonials that provide continuing identity with their Spanish ancestors. One Penitente writes,

> I am a member in good standing in the Brotherhood as were my forefathers, yet as is true of many Brothers of my generation, I no longer live in the village of my ancestors. Still I always return to the Morada. The Morada is a symbol of continuity, a reminder that those who went before us made many sacrifices to maintain something for succeeding generations (Wallis 1994).

Ancestral villages, archaeological sites, and petroglyphs, so numerous in the LANL region, are considered sacred areas by American Indian tribes. Pueblo de Cochiti inhabitants, for example, have many stories about their ancestors and the ruins in the region. Their stories indicate that originally all their people came up from Shipap (an unknown place of great antiquity) and lived together on the Mesa of the Stone Lions (Frijoles Canyon) in different villages: White House and the Village of the Two Lions (Benedict 1931, Akins 1993, and Douglas 1917). Then, the people split apart and the Santo Domingo went down the east bank of the Rio Grande to Cactus Village while the people of San Felipe, Laguna, and Acoma traveled west, down Peralta Canyon, and built the Pueblo of Peralta Canyon (Benedict 1931, Lange 1959, and Akins 1993). At the same time, the people of Cochiti went down Kapolin Canyon to settle in San Miguel on the west side of the river. Hainayasta and Tiputse are mentioned as Cochiti villages "across the river." Later the Pueblo de Cochiti people came from San Miguel to the "Plateau of the Buildings" where a new Pueblo was built. They lived there many years before coming down from the plateau (Benedict 1931 and Akins 1993).

Each of the physical places mentioned in such legends is a sacred link between the traditional community and the lives and traditional ways of their ancestors. The importance of ancestral villages is often reinforced by ceremonies held at ancestral ruins (Douglas 1917 and Akins 1993).

Natural Features

A variety of features in the landscape have special meaning for traditional cultures of northern New Mexico because of their association with the stories, myths, and legends that are shared by the community. Sites in this category may not need to be visited on a regular basis to retain cultural value and, in fact, may be inaccessible. The cultural value derives from the knowledge of their existence in relation to the ongoing history and values of the community.

Some natural features may resemble an animal, person, or mythological creature, and traditional stories may explain their existence and relationship to the traditional culture. Examples of this resource category include Camel Rock on Pueblo of Tesuque tribal lands and Black Mesa on Pueblo of San Ildefonso tribal lands. Black Mesa is known in stories as the home of Tsah-ve-yoh, a dreaded child-eating giant from Tewa stories, who returns to the surrounding Pueblos every year at Christmas time to whip any bad children who do not behave (DeHuff 1931). The same feature is also known from Tewa legends as a stronghold to which the people fled during the Navajo siege of ancient times and again when the Tewa were besieged by the Spaniards in 1694 (DeHuff 1931). Black Mesa does not have to be visited to maintain cultural value for the communities; its visibility is a daily reminder to children of the need to be obedient members of the Pueblo and of the bravery of their ancestors. Camel Rock, along U.S. Highway 84 between Santa Fe and Pojoaque Pueblo, is likewise a TCP that is mentioned in stories of the Tsah-ve-yoh. It is told that the giant would take four long strides from Black Mesa to Pojoaque to grab up the children of the Pueblo, then sit down on the rock formation (Camel Rock) to eat them alive (DeHuff 1931).

Stories and myths of Pueblo de Cochiti mention other prominent natural features: "Cave Place" and Peralta Canyon are mentioned in stories as places where giants lived. The giants are known to carry Cochiti children from the old Pueblo at Hainaysta (across the river from the modern Pueblo) through "Fissure Place" and to the "Giants Boiling Place." One giant, Schkoio schkaka haush, is known in myths to have been killed and shut up in his cave (Benedict 1931). Another natural feature is the "Stone Lions," a stone carved to resemble two resting lions, which gives the name "Village of Stone Lions" to an ancient Pueblo on the mesa above Frijoles Canyon (Hendron 1946 and Benedict 1931).

Mountain peaks, lakes, springs, and petroglyphs are often natural features in the sacred legends of traditional cultures in northern New Mexico (Akins 1993). Sacred peaks are part of the iconography of the Navajo Nation and of the Jicarilla Apache Tribe (Nordhaus 1995). Peaks sacred to the Tewa tribes include Conjilon, Chicoma Mountain, Sandia Crest, Truchas Peak (Friedlander and Pinyan 1980), San Antonio Peak, Lake Peak, and Cerro Pelado (Hewett and Dutton 1945). Sandia Pueblo considers Puye National Monument pictographs to be sacred to the tribe (Parker 1993). Hewett and Dutton reported in 1945 that the San Ildefonso and other Pueblos hold five area lakes and springs to be sacred (Hewett and Dutton 1945). These springs and lakes mark the four directions around San Ildefonso.

Ethnobotanical Gathering Sites

American Indian and traditional Hispanic communities rely on the use of wild native plants for ceremonial and medicinal purposes such as foods, dyes, and utilitarian objects (Dunmire and Tierney 1995, Robbins et al. 1916, and Toll 1992). Through the everyday use of native plants, there is a sense of connection with the land and continuity with the previous generations who were part of the land (Ford 1976, Cajete 1994, and Wetterstrom 1986). The continued use of botanicals in traditional cultures confirms a body of unwritten knowledge about the values and purposes of plants as part of a particular world-view or belief system unique to each culture (Wetterstrom 1986 and Toll 1992). This subsection contains information regarding plants that are ingested or used for ceremonial purposes. Plants used for dyes, construction, and other utilitarian purposes will be discussed as artisan materials in the following subsection.

American Indian ceremonies make use of specific wild plants and cultivated plants as foods, beverages, smoke, and coloring agents, or for ritual chewing. They are also incorporated into ceremonial implements or objects (Hiles 1992, Moerman 1986, and Dunmire and Tierney 1995). One such example of ceremonial use occurs each year at Sandia Pueblo when bundles of wood and snakeweed are taken to the cacique or Pueblo leader. This is done for 12 days following the winter solstice in ceremonies to nurture and bless the village (Dunmire and Tierney 1995). The use of smudges of big sage is recorded from Jemez Pueblo and the Navajo Nation for fumigating and purifying houses (Young 1940 and Dunmire and Tierney 1995). Douglas fir boughs and branches are incorporated into the traditional dances of several Rio Grande Pueblos (Dunmire and Tierney 1995), and cattails are also frequently featured in Pueblo ceremonies because of their symbolic association with water (Ford 1968 and Robbins et al. 1916). Navajo ceremonies use several plants such as bitterball and ironwood (Young 1940 and Elmore 1944). Ceremonial use of plants may require that they be gathered from specific places in order to increase their potency or ritual significance (Ford 1968). Pueblo practices may require ritualized gathering of medicinal plants and wild foods or may be undertaken only by certain sodalities (Ford 1968).

It is uncertain from the literature if there are Hispanic ritual or ceremonial uses for plants. Knowledge about the use of native food plants was undoubtedly shared among the Pueblo cultures and the Spanish colonists, for Hispanic knowledge and use of native plants for food and medicine overlaps a great deal with Pueblo uses. Pueblo uses of wild plants also seem to have been altered by Spanish contact (Toll 1992 and Ford 1968).

The Rio Grande Pueblo people gather many wild plants as foods and beverages (Dunmire and Tierney 1995). Documented food use includes three-leafed sumac, acorns from Gambel's oak, and ripe fruit from the chokecherry, gooseberry, and currant. Since ancient times, the fleshy fruit of the banana yucca has continuously been harvested and used as food by Pueblo people (Minnis 1991, Ford 1968, Toll 1983, and Toll 1992). The use of Indian tea is also very common as a beverage among Pueblo, Navajo, Apache, and Hispanic people in the region (Dunmire and Tierney 1995, Moerman 1986, and Elmore 1944). Prickly pear fruit, Indian rice grass seeds, and tubers of wild potato are believed to have been important "famine foods" of the region in past times of drought and may still be gathered and encouraged to grow near Pueblos (Minnis 1991). Pinyon nuts are the most important of all wild food sources for Pueblos and traditional Hispanic communities in the region. Families will frequently travel great distances to collect nuts in the autumn, and individuals may gather and sell the nuts in their communities (Ford 1968 and Dunmire and Tierney 1995).

Medicinal use of wild plants is common in northern New Mexico among the Pueblo, Apache, and Navajo people and traditional Hispanics. Dunmire and Turney (1995) assert that 180 different species of wild plants in the region have medicinal uses among 1 or more of the 19 New Mexico Pueblos. Regular medicine gathering trips are conducted to the Pajarito Plateau and other high elevation sites by the Pueblo's medicine societies (Dunmire and Tierney 1995 and Ford 1968). Commonly known medicinal plants include joint-fir, broom snakeweed, sage, and four-o'clocks (Dunmire and Tierney 1995 and Curtin 1947). Osha root is also an important medicinal plant used by American Indians and Hispanics in the region (Ford 1968, Hiles 1992, and Dunmire and Tierney 1995). The locations of collection areas for some of the rarer medicinal plants that grow in the mountains, such as Osha root, may be a closely kept secret of village healers.

Artisan Material Gathering Sites

The gathering of raw materials for numerous commercial and non-commercial utilitarian objects is common in the American Indian and Hispanic traditional communities. While some utilitarian objects, such as handmade plant fiber cordage, woven yucca sandals, and wooden arrowheads, have generally been replaced by modern products, there are still enduring traditions of weaving, tanning, wood carving, jewelry making, joinery and construction, and pottery making that use native materials gathered locally. The products of these traditional arts have become internationally prized not only because of the aesthetic quality they demonstrate, but also because of their continued use of native woods, fibers, dyes, and minerals. The continued access of traditional communities to the natural resources of the region is vital to the continuation of these traditional arts.

The use of natural dyes, pigments, and tanning agents is still a characteristic of traditional American Indian and Hispanic communities in northern New Mexico (Dunmire and Tierney 1995 and Dickey 1990). Weaving is a very important traditional art form, and many traditional weavers still produce dyes from native plants they have gathered locally (Dickey 1990, Minge 1979, and Dunmire and Tierney 1995).

Three of the important dyes used by traditional Hispanic weavers are imported from Mexico: indigo, cochineal, and brasilwood (logwood) (Anonymous 1976 and Minge 1979). Other important dye-producing plants are gathered from village roadsides, acequia banks, mountain habitats, or the nearby desert (Dunmire and Tierney 1995 and Dickey 1990). These plants include goldenrod, cocklebur, sumac, sunflower, dahlia, chokecherry, chamisa, snakeweed, slatbush, mountain mahogany, oak and alder bark, lichens, caniegra, Virginia creeper, cota or Indian tea, juniper, madder, black walnut, onion skins, and marigold (Anonymous 1976, Minge 1979, Dunmire and Tierney 1995, and Young 1944). Rocky mountain beeplant, wild dock, pinyon pitch, and tansy mustard are used for pottery paints (Dunmire and Tierney 1995), and red clay is sometimes used as a red fabric dye (Young 1944).

Construction woods and adobe clays are also gathered from sources in northern New Mexico. Pueblo and traditional Hispanic construction uses whole logs for vigas (roof beams) made of cottonwood, Ponderosa pine, and Douglas fir (Dickey 1990 and Dunmire and Tierney 1995). Latillas (roof cross-supports) are usually made of split aspen, mountain-mahogany, or oak; roof thatching is made of four-winged saltbush or common reeds (Young 1944, Dickey 1990, and Dunmire and Tierney 1995).

Adobe clay is gathered from many sites near Pueblos and Hispanic villages and mixed with dried plants to form the walls of most buildings in traditional communities (Dickey 1990, Weigle 1978, and Hill 1982). Potter's clay, however, comes from very specialized sites that contain very fine clays without impurities (Dickey 1990 and Peterson 1977).

Wood carving is an artistic tradition in some Hispanic communities (Briggs 1980), and carved wooden Santos are an important tradition of the local churches and Moradas (Dickey 1990 and Briggs 1980). Santos are carved depictions of the saints and allegorical stories in the Catholic traditions and traditionally are of two forms: bultos, or three-dimensional carvings; and retablos, or bas-relief carvings on hinged wooden panels (Briggs 1980). The wood may be augmented with gypsum, metals, and other materials. Paints were originally of natural pigments, but increasingly include commercial products (Briggs 1980). Native wood of outstanding carving characteristics is gathered from the national forests. Preferred wood comes from aspen, berried juniper, willow, and pine (Briggs 1980).

Drums and many other articles are carved from the aspen and cottonwood found in the Pueblo communities (Dunmire and Tierney 1995), and bows are made from pliable woods such as wild currant, New Mexico locust, and chokecherry (Dunmire and Tierney 1995). Arrows are crafted from various woods and common reeds. Apache plume is most commonly used for making brooms (Dunmire and Tierney 1995).

E.3.3.4 *Traditional Subsistence Features*

Traditional subsistence practices in use in northern New Mexico include community-maintained irrigation ditches, called acequias, traditional trails and hunting areas, traditionally used fields, grazing areas, firewood-gathering sites, and Spanish land grants. While subsistence functions may not be unique to tribal or Hispanic communities, the traditional community is often brought together and identified through their annual subsistence cycle, and these subsistence activities reinforce a world-view and values unique to the community. As such, the protection of these properties ensures the ability to continue traditional community values and identity.

Acequias are the best known example of traditional subsistence features in northern New Mexico. Acequia communities are complex social institutions that have developed around the Hispanic water supply and irrigation systems known as the Acequia Madre (Arellano 1994). Irrigation systems require not only a sedentary lifestyle but also a complex system of social participation and control because of the intense labor required to build, maintain, and regulate them. Many areas in the arid southwest have developed unique traditional practices surrounding the acquisition of water rights and the development and use of irrigation systems. In northern New Mexico, the acequia communities have developed through the commingling of Pueblo and Spanish traditions and the particular demands of the environment (Campa 1979 and Jenkins 1972).

The fertile flood plains of northern New Mexico required tapping the rivers for a reliable water supply for people, crops, and livestock. Wide fluctuations in annual rainfall characterize the region, making the regulation of hydrological systems essential for a sedentary population (Ackerly et al. 1993). Irrigated agriculture, including terraces and reservoirs, has been present in the Rio Grande Valley since A.D. 1400. The Tewa Pueblos produced crops of maize, squash, beans, melons, cotton, and chile using simple but effective irrigation techniques (Arellano 1994). In an early expedition into northern New Mexico, Antonio Espejo observed the agricultural systems at Acoma Pueblo, stating that they had "... found many irrigated corn fields with canals and dams" (Hammond and Rey 1966).

The Spaniards were already familiar with a variety of irrigation techniques dating back to the Roman and Moorish civilizations. In the years after Spanish settlement of northern New Mexico, they augmented native methods of irrigation with those brought from the Iberian peninsula, including social community cooperation and control mechanisms. Eventually, the physical and social practices of Hispanic irrigation became codified legal institutions as well as traditional cultural systems. These are still reflected in New Mexico water law, as well as in the traditional practices of some Hispanic communities.

Acequia systems did not develop without a good deal of contention and social conflict. Spanish and Pueblo traditions differed considerably in the cultural perspective on the relationship of water, religion, and society. Early Spanish water tradition was relatively compatible with Pueblo traditions in that water resources were considered to belong to the community rather than the individual (Ackerly et al. 1993). The concept of the community gradually gave way to privatization and the pursuit of private wealth in the New World (Meyer 1984). Conflicts over water rights and the shared responsibility for acequia maintenance among the Spanish

Colonials increased over time, as did conflicts over water rights between acequia users and neighboring Pueblos.

Article 6 of the *Plan de Pitic*, 1789, specified that all new lands in the northern provinces, subject to irrigation, would receive equal benefits of water from the Acequia Madre through individual outlets and ditches (Meyer 1984). Each landowner, or parcipiante, was to be informed of his outlet location and was not to abuse any neighbor's access to water. Outlets were to be made of stone and mortar, at the individual's expense, to prevent losses to downstream users. Article 19 of the *Plan de Pitic* specifies the fair apportionment of water to the community. Responsibility is given annually to the town council to appoint an overseer, called the alcalde or mayordomo, for each outlet of the Acequia Madre. This person was to apportion the water to all fields in proportion to the needs of each, with each individual landowner having posted hours for irrigation. The alcalde was authorized to hire an assistant to check the outlets for compliance at the proper times and to charge a fee to the landowner if the assistant was required to open the outlet for him. This basic political/agricultural institution has been followed by Hispanic and Hispanic-influenced communities in Texas, California, parts of Colorado and Arizona, as well as throughout New Mexico (Meyer 1984).

The affairs of the acequia are handled in many Hispanic areas of New Mexico at meetings of La Junta del Agua, a problem-solving-oriented assembly of landowners. This tradition dates back to the Tribunal de las Aguas, which met regularly since the Middle Ages on the steps of the Cathedral of Valencia, Spain, (Campa 1979). The members of La Junta del Agua were respected members of the community. Within this context, important issues of water rights and local power were decided. All the landowners using water from the Acequia Madre still gather in the spring with horses, scrapers, and manpower to clear out debris and rocks and to make any necessary repairs (Meyer 1984). This communal activity, guided by the mayordomo, is called La Fatiga in New Mexico and is often a significant community event for Hispanic villages (Campa 1979).

Pueblo irrigation predates Spanish contact. Centuries of excavation, routine maintenance, and repairs mask any clear-cut evidence of their prehistoric origins (Ford 1976 and Meyer 1984). Acequias are integral to the technological and ceremonial life of the Pueblo. Their use, while very similar to the use in the Hispanic communities, is punctuated by religious and ceremonial events unique to each Pueblo (Ford 1968, Ford 1976, and Hill 1982).

Land grants form the basis of title and land use for many of the traditional communities in northern New Mexico. Land grants were dispensed by the Spanish Crown and Mexican government to the Pueblos and to Spanish settlers "to advance civilized life" in the region. The land grants were of three types: those for individual tracts of irrigable farmland, those that were granted as commons or pasture lands for a community, and those that were given to each Pueblo to regulate for their own purposes (Leonard 1970). The Pueblo land grants only affirmed the Pueblos' rights to existing patterns of land use, but the Hispanic land grants, upheld by U.S. law, shaped the lifestyles of traditional communities in the region (Leonard 1970 and Carlson 1990). Modern Pueblos, including their fields and commons, are considered to be TCPs in their own right. Traditional Hispanic land grant communities may also be considered TCPs in that all of the parts (e.g., individual holdings, commons, acequias, village) are interrelated and required for the continuation of the whole (Leonard 1970, Carlson 1990, Ackerly et al. 1993, and Arellano 1994).

An example of an existing traditional Hispanic Land Grant community in the LANL region is the Canyon de San Diego Land Grant near Jemez Springs (Cline 1972). The grant includes 110,000 acres (44,517 hectares) of commons or grazed community lands and 6,000 acres (2,428 hectares) of individual farms irrigated by acequias (Cline 1972). The individual farms were granted as parcels along the acequia system. Over generations, the allotments have been further divided as a result of inheritance practices into thin parcels called strip holdings or long fields (Carlson 1990 and Cline 1972). Each borders the acequia on a narrow side. The village is thus characterized by the existence of long fields in the bottomland where corn, beans, squash, alfalfa, and other crops are irrigated by the acequias (Carlson 1990 and Weigle 1978). The acequias and the grazing commons are the shared responsibility of the villagers, and the commons provide not only grazing for livestock but also many other natural resources gathered by individual families (Weigle 1978 and Carlson 1990). Pinyon nuts, firewood, construction wood, ethnobotanicals, and other resources come from the commons, which are frequently mountainous (Carlson 1990). The houses and church or Morada of the village are clustered tightly, reducing any waste of valuable bottomland and providing community solidarity. The routine of community life is punctuated by agricultural, irrigation and religious events, and is broken by periodic treks into the mountains to gather wood and other resources. All elements are necessary not only for subsistence but also to maintain a unique cultural identity in the face of the modern cash economy.

Traditionally used trails and hunting areas form another subsistence element of traditional cultures of northern New Mexico, particularly of the American Indians. Communal hunts are conducted by Pueblo sodalities or moeities, which are often ritualized and geographically specific (Ford 1968). The mountains are generally shared territory among several tribes. Not only are they areas to hunt or gather specific plants, but they are also locations of important shrines with ritual obligations for visitation (Ford 1968 and Nordhaus 1995). Trails to hunting sites, ceremonial sites, and grazing areas were documented for the Jicarilla Apache Tribe (Nordhaus 1995), and Harrington's maps of Pueblo sites also show trails (Harrington 1916). Zuni trails are indicated on a map by Ferguson and Hart (1985). Their trails lead as far as the Great Salt Lake in Utah. The Zuni tribe has also documented ritual hunting areas and deer trap areas (Akins 1993 and Ferguson and Hart 1985).

E.4 Federal and State Regulations Related to Cultural Resources at LANL

The NHPA (16 U.S.C. §470) was passed in 1966. Under the NHPA, federal agencies (in this case, DOE) have specific responsibilities toward cultural resources that are on their lands or that may be affected by their activities. Section 106 of the NHPA requires that DOE take into account the effects of activities on significant cultural resources. DOE is also required to allow the Advisory Council on Historic Places (ACHP) the opportunity to comment on any DOE plan that may affect such resources. Under the ACHP's regulations for implementing Section 106 of the NHPA (published in the Code of Federal Regulations as 36 CFR 800), the ACHP's right to comment is often delegated to the SHPO. The regulations specifically require that DOE identify cultural resources that may be affected by its "undertakings," evaluate the significance of those resources, and assess the effects of its undertakings on those resources. This process must be completed in consultation with the New Mexico SHPO.

Under Section 106, cultural resources are considered significant if they are eligible for inclusion on the NRHP. Federal regulation 36 CFR 60.4 states that cultural resources may be eligible to the NRHP if they meet one or more of the following criteria:

- They are associated with events that have made a significant contribution to the broad patterns of history.
- They are associated with the lives of persons significant to our past.
- They embody the distinctive characteristics of a type, period, or method of construction, or they represent the work of a master; possess high artistic values, and/or represent a significant and distinguishable entity whose components may lack individual distinction.
- They have yielded or may be likely to yield, important information to prehistory or history.

The SHPO and other personnel of the Historic Preservation Division of the New Mexico Office of Cultural Affairs, operate under the NHPA and in particular monitor Section 106 compliance. The Historic Preservation Division also provides technical services, a state-wide database, and Section 106 compliance advisors (18 New Mexico Statutes Annotated [NMSA] §6–1 through 6–17 and 8–1 through 8–8). In addition to assisting DOE in determining cultural resource significance, the New Mexico SHPO is responsible for coordinating state participation in implementing the NHPA (16 U.S.C. §470). The New Mexico SHPO represents the interests of the state and its citizens in the preservation of their cultural heritage and assists DOE in identifying historic properties and assessing impacts of activities. The SHPO may agree or disagree with the responsible agency's assessment of the eligibility of its cultural resources. Ultimately, the determination of eligibility of any cultural resource is made by the keeper of the National Register, DOI (36 CFR 63.2).

To determine the scope of the SWEIS cultural resources evaluation, DOE first met with the New Mexico SHPO. The meeting resulted in a decision that the SWEIS does not, in and of itself, constitute an undertaking; therefore, compliance with Section 106 of the NHPA (16 U.S.C. §470) is not required (PC 1996). However, individual actions covered by the SWEIS might be undertakings requiring Section 106 compliance.

Through development of the LANL SWEIS, the DOE evaluated the potential impacts of proposed actions on cultural resources in order to mitigate impacts, if required, and to ensure compliance with all applicable federal and state requirements.

Of interest in this process are actions that might adversely affect or diminish the integrity of the location, design, setting, materials, workmanship, feeling, or association of a TCP. Adverse effects evaluated for the SWEIS include, but are not limited to

- Physical destruction, damage, or alteration of all or part of the property.
- Isolation of the property from or alteration of the character of the setting when that character contributes to the qualification of the property for nomination to the NRHP.
- Introduction of visual, audible, or atmospheric elements that are out of character with the property or alter its setting.
- Neglect of the property resulting in deterioration or destruction (36 CFR 800.9).

The scientific community has concerns that compliance with federal historic preservation law might impede efforts to remain at the forefront of international research and achievement. In 1989, in response to these concerns, Congress directed the ACHP to study the designation of scientific research institutions as historically significant. Concerns were raised by agencies faced with altering or renovating existing or abandoned research facilities that were considered eligible for the NRHP by the ACHP. The resulting document, titled "Balancing Historic Preservation Needs with the Operations of Highly Technical or Scientific

Facilities," discusses the needs of research institutions to upgrade their facilities and the responsibilities of preservation agencies to implement the requirements of federal historic preservation regulations (ACHP 1991). The following are among the recommendations outlined in the 1991 report:

- Future authorizations for major scientific and technological programs should include public education components focusing, in part, on the communication of the relevant history of science.
- Decisions about projects that may affect historic properties need to be made with as complete an understanding as possible of those effects. However, considerations of preservation options should be kept distinct from the peer review process of awarding research grants and the determination of research priorities central to the scientific research process.
- The ACHP and affected federal agencies should jointly subscribe to a statement of policy that acknowledges the sensitive relationship between scientific research and the evolving history of science and its physical manifestations.
- Federal agencies should determine how they might better coordinate historic preservation programs and planning among facilities managers, public affairs officers, archivists, historians, external affairs officers, and other staff. The ACHP should recommend measures to these agencies to improve the effectiveness, coordination, and consistency of procedures with the purposes of the NHPA (16 U.S.C. 470 §202[a][6]).
- Future scientific achievement, as well as adequately serving the public interest, depends on an understanding of past scientific successes and failures. Federal agencies, in cooperation with other concerned parties, should explore innovative ways for minimizing and meeting the costs of historic preservation that may be associated with the operations and management of historic facilities.
- The ACHP, in cooperation with the Smithsonian Institution, the NPS, and federal agencies, should establish a consensus about what kinds of scientific facilities and objects should be physically preserved for the future. This should include deciding how the historic value of facilities and objects can be determined and which facilities and objects can be "preserved" through documentation. The ACHP suggests that the documentation option would be best suited to historic facilities that are still active.

The study concluded that the ACHP regulations and the Section 106 review process are flexible enough to accommodate the legitimate needs of the scientific and engineering community and their activities at historic facilities (ACHP 1991).

The NPS's *National Register Bulletin 22*, "Guidelines for Evaluating and Nominating Properties that Have Achieved Significance Within the Last Fifty Years" (NPS 1990), emphasizes the importance of carefully establishing the cultural context of properties and evaluating them based on comparisons with other possible properties within the same historical context. A justification or rationale of exceptional importance should be an explicit part of a statement of significance. Such properties frequently qualify for nomination to the NRHP under more than one of the criteria for evaluation for nomination (36 CFR 60.4).

The NPS's *National Register Bulletin 38*, "Guidelines for Evaluating and Documenting Traditional Cultural Properties" (Parker and King 1990) indicates that objects, trails, pathways, physical features, or resource gathering sites that are significant to a living community's historically rooted beliefs, customs, and practices, may be eligible for protection under the NHPA. Within LANL's boundaries, TCPs exist that have both a current and a traditional importance to existing American Indian and other local communities. Although TCPs have been eligible for the NRHP since its creation (Parker 1993), it was not until *National Register Bulletin 38* was published that their importance was recognized by federal agencies, SHPOs, and other cultural resources managers.

Other pieces of legislation, including the AIRFA of 1978 (42 U.S.C. §1996), the NAGPRA of 1990 (25 U.S.C. §3001), and Executive Order (EO) 13007, deal mostly with religious, ceremonial, or burial sites.

The AIRFA is a joint resolution of Congress stating that the policy of the U.S. is to protect and preserve the right of American Indians to have access to sites, possess and use sacred objects, and worship through traditional rights and ceremonials. The AIRFA is simply a policy statement; no regulations implementing the AIRFA have been promulgated. (However, within DOE, DOE Order 1230.2, *American Indian Policy*, is the implementing regulatory mechanism.)

The NAGPRA places ownership or control of American Indian human remains or funerary objects, excavated or discovered on federal or tribal lands after the date of the act, in the hands of the lineal descendants of the Indian tribe. Moreover, the NAGPRA requires agencies and museums with collections of American Indian human remains or associated funerary objects to inventory those remains; identify their geographic and cultural affiliations, in consultation with tribal governments and religious leaders. They then must provide each Indian tribe with a copy of the inventory of remains associated with that tribe, an inventory of remains not clearly associated, and access to records, catalogues, and studies. If the cultural affiliation is established or demonstrated through "geographical, kinship, biological, archaeological, anthropological, linguistic, folkloric, oral traditional, historical, or other relevant information, or expert opinion" (43 CFR 10.7[a][4]), the remains must be returned, if requested. The regulations implementing the NAGPRA, published in 1995 (43 CFR 10), provide a systematic process for determining the rights of lineal descendants and Indian tribes to the remains, and instructions for consultation.

Consultation with lineal descendants and affiliated tribes is required at several stages of NAGPRA compliance. Intentional archaeological excavations of human remains, funerary objects, sacred objects, or objects of cultural patrimony on federal lands are permitted only after consultation with appropriate Indian tribes (43 CFR 10.3). Consultation must include any tribes that are likely to be culturally affiliated with or to have occupied the area, or that have a demonstrated cultural relationship to the remains (43 CFR 10.5). Prior notification of Indian tribes who have likely affiliation, have aboriginal use of the area, or who are otherwise culturally related to the remains is required if an activity may result in the excavation of such remains (43 CFR 10.3[c]). Inadvertent discoveries require notification of "likely to be culturally affiliated" Indian tribes within three working days and cessation of all disturbance in the area. In addition, the person or agency responsible for the discovery must protect the site from further disturbance. The project may resume in 30 days after notification unless a plan, such as a memorandum of agreement (MOA) is in place. In the event of emergency discoveries, consultation should be coordinated with the reporting responsibilities of other legislation. Additionally, 43 CFR 10.6 recommends that federal agencies enter into comprehensive agreements with Indian tribes, addressing all federal agency land management activities that could result in the intentional excavation or inadvertent discovery of such remains, and that they establish a process for effectively carrying out the NAGPRA requirements. LANL has completed an inventory in compliance with the NAGPRA;

however, to date, the NAGPRA consultations have included only the four Accord Pueblos.

EO 13007 directs agencies to accommodate access to and ceremonial use of Indian sacred sites on federal lands by Indian religious practitioners, and to avoid adversely affecting the physical integrity of such sites. A sacred site is defined as a "discrete, narrowly delineated location of federal land that is identified by an Indian tribe, or Indian individual determined to be an appropriately authoritative representative of an Indian religion, as sacred by virtue of its established religious significance or for ceremonial use by an Indian religion." EO 13007 is applicable to some TCPs and adds protection to newly established ceremonial sites; however, it does not apply to subsistence features, artisan gathering sites, and ethnobotanical gathering sites.

Within 1 year of the effective date of EO 13007, the head of each agency was directed to report the following to the President:

- Changes necessary to accommodate access to Indian sacred sites.
- Changes necessary to avoid adversely affecting the physical integrity of sacred sites.
- Procedures implemented or proposed to facilitate consultation with appropriate Indian tribes and religious leaders and resolution of disputes.

A draft report for compliance with EO 13007, prepared by DOE in May 1997, states that DOE will accommodate access to sites by working directly with tribes to identify their needs for access or barriers to access, developing MOAs with tribes, and developing and implementing cultural resource plans in consultation with tribal officials. Changes necessary to avoid adversely affecting Indian sacred sites are continuing outreach to tribes to expand DOE's ability to identify sites, to develop and to implement cultural resource plans in consultation with tribes, and to incorporate tribal representatives into cultural resource planning. Consultation with Indian tribes will be facilitated by training DOE personnel, with assistance from tribal members; developing specific consultation procedures or using existing procedures such as those for the *National Environmental Policy Act* (NEPA) (42 U.S.C. §4321) and Section 106 compliance, and seeking to resolve disputes with tribes.

Other legislation explicitly requires inventories of significant resources. Section 110 of the NHPA requires agencies to inventory significant sites under their jurisdiction and to develop plans to manage those resources. Also, EO 11593, §2(a) (1971) orders agencies to "locate, inventory, and nominate to the Secretary of the Interior all sites, buildings, and objects under their jurisdiction or control that appear to qualify for listing in the NRHP." Furthermore, it directs agencies to submit to the Secretary of the Interior procedures for the maintenance and preservation of historic and archaeological sites under their control (EO 11593, §2[d]). This legislation forms the basis for protecting cultural resources.

E.5 RESEARCH METHODOLOGY

Anthropologists and historians have developed the concept of historical context as a framework to facilitate the evaluation of significance. Historical context facilitates the evaluation process by grouping information about cultural resources based on a shared theme, specific time period, and geographical area (48 *Federal Register* [FR] 44739). Historical context provides a flexible and legitimate basis for site-wide planning decisions that may affect cultural resources, and is developed by the SHPO to provide a basis for evaluating prehistoric and historic sites by identifying patterns or research problems in the historical and prehistoric record. Patterns or research problems include (48 FR 44718–44719):

- The chronological period and geographical area of each context.
- A compilation of existing information obtained through literature and background searches.
- The identification of trends in research and cultural values of the settlement, architecture, and art.
- A definition of property or site types by characteristics of each type.
- The identification of gaps in the body of information concerning historical context.

Historical context, then, includes both temporal and spatial information as well as artifacts and structures. It is ideal for incorporating cultural resources into the SWEIS because it is nonjudgmental; it includes elements of significance without implicating sites or localities as significant or insignificant. While the development of context is beyond the scope of the SWEIS, the SWEIS research methodology used the paradigm outlined above to categorize cultural resources.

Historical contexts are not well defined for New Mexico. Researchers in the state generally apply a research design published in 1981 by the State of New Mexico, Office of Cultural Affairs, Historic Preservation Division, titled "Prehistoric New Mexico; Background for Survey" (Stuart and Gauthier 1981). Although this research is applicable, it lacks the framework to evaluate site significance that is intended for contexts. Several Historic Period contexts were defined in a manuscript titled "New Mexico Historic Contexts" (Pratt and Scurlock 1993). Pratt and Scurlock (1993) recommended the development of a nuclear energy context, extending in time from 1943 to the present and including Los Alamos, Albuquerque, the Trinity Site, and southeastern New Mexico, with associated property types (laboratories, reactors, nuclear development and testing sites, and waste storage sites). The absence of a defined nuclear energy context makes classification and evaluation of historic resources at LANL difficult and results in a data gap for the SWEIS and for the cultural resources management program at LANL.

E.5.1 Research Methods for Acquiring Data on Prehistoric Cultural Resources

Archaeological and cultural data on the existing prehistoric cultural resources at LANL were acquired from the LANL Cultural Resources Management Team; the New Mexico Office of Cultural Affairs, Historic Preservation Division; the New Mexico State Register of Cultural Properties; and the Museum of New Mexico, Laboratory of Anthropology, Archaeological Records Management Systems (ARMS). A review of published records and literature about the history and cultures of northern New Mexico was also conducted as part of the SWEIS.

Comprehensive data on cultural resources at LANL are maintained in paper and electronic databases and Geographic Information System (GIS) by the LANL Cultural Resource Management Team and include both compliance information and cultural/ archaeological data (PC 1995). The LANL Cultural Resources electronic database was reviewed. Some sites have been recorded or confirmed recently by the LANL Cultural Resource Management Team, while others have been previously recorded, using methods and controls that may be different from present standards. Sites are classified in the electronic database according to available information on location, site type, and eligibility status. They are not, however, classified according to age or cultural affiliation. Cultural resource data are transferred, using site forms, from LANL to the New Mexico ARMS database at the Museum of New Mexico, Laboratory of Anthropology. A lag of approximately 10 years exists in the processing and transfer of some data to ARMS, resulting in differences in the numbers of sites in each electronic database as well as in the types of information conveyed in each database.

Attempts were made to reconcile the two electronic databases in order to obtain information about the historical context of prehistoric resources and the numbers and types of cultural components of each site. Discrepancies were found between the two electronic databases that prevented the inclusion of ARMS data in the SWEIS. Therefore, the site numbers, locations, and site type data provided by the LANL Cultural Resources Team form the basis of this study. Prehistoric resources were incorporated into a GIS for overlay impacts analysis. Methods were developed to ensure that sensitive cultural resource information was not jeopardized during the study.

E.5.2 Research Methods for Acquiring Data on Historic Cultural Resources

Data on Historic Period resources were obtained from several sources. Data relating to the Spanish Colonial and U.S. Territorial periods were obtained from the LANL Cultural Resource Management Team database and publications. Data about cultural resources constructed at LANL during the Nuclear Energy Period were obtained from the LANL report, *Capital Asset Management Process, Fiscal Year 1997* (LANL 1995a), the Facility for Information Management, Analysis, and Display (FIMAD) database (LANL 1996), the as-built structure location maps for LANL (GITL 1997), the Environmental Restoration Program Decommissioning Summary Site Plan (LANL 1995b), and the LANL Cultural Resource Management Team database and publications. The locations of known structures dating from the Nuclear Energy Period were determined from facility maps and incorporated into a GIS for overlay impacts analysis. These data do not include non-building remains of those periods and do not fully identify the numerous interrelated infrastructure support systems and functional systems present at LANL. The LANL Cultural Resource Management Team has a database of potential historic facilities that includes many existing and demolished structures (LANL Cultural Resource Database). These data have been excluded from the list of known resources until further documentation can be obtained to link them with the historical context of the Nuclear Energy Period.

E.5.3 Research Methods for Acquiring Data on Traditional Cultural Properties

TCPs were studied, using methods designed to identify categories and specific resources, to assess potential impacts from LANL operations and to provide recommendations to protect those resources from adverse effects from future LANL activities. The purpose of the study was to determine if properties exist within the LANL region that continue to hold cultural significance to those groups claiming traditional use or affiliation with the LANL area. TCP identification, evaluation, and documentation processes were conducted using the guidelines specified in *National Register Bulletin 38* (Parker and King 1990), which addresses eligibility to the NRHP. Natural, physical, biological, political, ideological, and man-made places significant to the local communities for ideological, economic, or historic reasons were identified in this study.

The goals of the SWEIS TCP study were to identify:

- Those American Indian, Hispanic, and other communities with cultural affiliations in the LANL area.

- The types of TCPs in the LANL region that could be affected by LANL and the kinds of LANL activities that could affect them.
- Potential avenues of mitigation that would avoid or minimize impacts to traditional properties.

The primary focus of the TCP study was American Indian and Hispanic traditional communities. However, if TCPs associated with other cultures or groups were identified during the course of this study, they were also acknowledged here.

The TCP research methods used in this study include the following elements:

- *Identify Traditional Communities That Maintain Affiliation with or Traditional Use of the LANL Area*. A 50-mile (80-kilometer) radius around LANL was used to identify communities to establish consultations. Other communities identified through the literature review were then added to the list.
- *Conduct Initial Consultations with Potential TCP Communities*. This level of consultation includes identifying appropriate contacts, making telephone calls, and setting up meetings with communities to introduce the SWEIS and inquire about their desire to participate in the SWEIS process.
- *Enter into Agreements for TCP Community Consultations*. Interested traditional communities established the methods for identifying TCPs of concern to them in the LANL area. Most traditional communities completed TCP field survey forms and provided either written or oral commentary on the cultural resource reference materials used in preparing sections of the Draft SWEIS. Participating traditional communities had review and editing rights regarding sensitive information prior to publication.
- *Review Ethnographic Literature*. Ethnographic literature was reviewed to understand the range and types of TCPs for selected traditional communities that have documented affiliations to the study area or have expressed a cultural affiliation to the affected environment on the basis of TCP community histories. The list of American Indian cultures covered in the ethnographic literature review includes approximately 17 Pueblo and Athabaskan cultures that have vested interests in the protection of traditional places in the LANL region. These cultures include the following:
  - — Pueblo of Nambe
  - — Hispanic Communities
  - — Pueblo of Taos
  - — Pueblo de Cochiti
  - — Pueblo of Picuris
  - — Pueblo of Jemez
  - — Pueblo of San Ildefonso
  - — Pueblo of Sandia
  - — Jicarilla Apache Tribe
  - — Pueblo of Santo Domingo
  - — Pueblo of San Juan
  - — Pueblo of Zia
  - — Pueblo of Santa Clara
  - — Pueblo of Zuni
  - — Pueblo of Pojoaque
  - — Hopi Tribe
  - — Pueblo of Tesuque
  - — Navajo Nation
- *Conduct the Consultations with Communities or Groups Identified*. Consultations are meetings held within the potentially affected community. They include community/tribal representatives, leaders, elders, and resource specialists identified during the research and networking efforts outlined above. A field survey form was designed to facilitate discussions with traditional communities, assist in the recording and classification of TCPs, record concerns of potential effects of LANL operations, record suggestions for

mitigation measures, and suggest methods to preserve TCPs. The methods used at TCP consultations were flexible in order to respond to the needs of different communities. For example, some communities conducted their own consultations. A Consultation Recording Sheet and a map showing LANL and surrounding areas were left with the communities. The consultations were completed by community members or staff and returned to the researchers.

- *Identify and Contact Traditional Hispanic Community Leaders*. Similar to Pueblo/ Tribal consultations, consultations with Hispanic weavers, herbalists, lay-brotherhood members, artisans, acequia (shared community ditch) commissioners, mayordomos/mayordomas, and acequia federation offices were conducted to obtain information for the TCP study, solicit participation, and make possible the assessment of impacts. Consultations were conducted by letter, follow-up phone calls, group consultations, and site visits.
- *Identify and Invite the Participation of Regional Traditional Hispanic Organizations*. Hispanic organizations that represent the interests of traditional communities, such as artisan guilds, rural development organizations, and others were contacted and invited to participate in group consultations to identify Hispanic TCPs and possible impacts of LANL activities.
- *Conduct Hispanic Community Meetings and Interviews*. Hispanic TCPs were identified through two community meetings: one held in Jemez Springs, New Mexico, and the other held in Española, New Mexico. The general format of the meetings included a presentation on the goals and purpose of the SWEIS and definitions and examples of TCPs, followed by responses to questions regarding the TCP field survey forms. Records of the meetings were transcribed and submitted to the communities for review and comment.
- *Analyze Findings in TCP Field Survey Forms*. A classification system was developed for TCPs, based on the results of the literature search and consultations. This system was organized by category, including shrines, plant gathering areas, clay procurement areas for pottery making, hunting areas, technology sites (tool-making), and acequias. The analysis included synthesizing information from the literature review and consultations.
- *Review of TCP Information for the Draft SWEIS*. Consultations included a 30-day period to review the reference materials used for preparation of cultural resource sections of the Draft SWEIS. This was a separate review process that was limited strictly to the cultural resource sections. Upon receipt of review comments, the draft cultural resource sections were edited to reflect relevant comments.

E.5.4 Impacts Analysis Methods

The goals of the SWEIS cultural resources impacts analysis were to assess the general scale and intensity of impacts to the cultural resources from activity levels in each of the SWEIS alternatives. The cultural resource impacts analysis is not intended to take the place of project-specific NHPA and NEPA reviews, but to provide a comparative assessment of the impacts to cultural resources to be expected from each alternative.

The following parameters were established for impacts analysis:

- All cultural resources were considered in the cultural resource impacts analysis regardless of eligibility. These resources were from three broad categories: prehistoric archaeological sites, historic resources, and TCPs.
- The impacts analysis considers general categories of cultural resource types (e.g., simple and complex pueblos, scientific

laboratories, ceremonial sites) rather than impacts to individual resources. The types of effects and levels of adversity were determined for each resource class.

- Impacts are evaluated in a general manner and according to four broad categories that reflect the criteria of effect (36 CFR 800.9): destruction/alteration; isolation and restriction of access; introduction of visual, audible, or atmospheric elements out of character with the resource; and neglect leading to deterioration and vandalism. Not all classes of cultural resources will be affected by every category of effect.
- Adverse effects to any resource category were evaluated for each of the four SWEIS alternatives by means of a data matrix. Geographic overlay analysis and detailed project descriptions were used to assist in identifying the numbers and types of cultural resources that might be affected by the alternatives. Results of the consequence analysis for air quality, surface and groundwater, human health risk, and noise and vibration will be used to evaluate impacts to human users of TCPs and other potential impacts to cultural resources.
- Data from recent LANL operations were used as points of comparison for the relative severity of cultural resource impacts under each alternative. The degree of adverse impacts were qualitatively assessed according to the approximate number of resources adversely affected, the intensity of the impact, and the duration of the impact.

Table E.5.4–1 summarizes the potential for effects of various actions on categories of prehistoric cultural resources found at LANL. Table E.5.4–2 provides the potential for effects of various actions on historic resources at LANL, while Table E.5.4–3 gives the potential for effects of various actions on TCPs. LANL operations and projects reflected in the SWEIS alternatives were evaluated according to their potential effects on nearby resources, as described in these tables.

E.6 EXISTING CONDITIONS FOR CULTURAL RESOURCES AT LANL

The following subsections contain discussions of LANL's cultural resource management and the existing prehistoric, historic, and traditional cultural resources within the boundaries defined in the SWEIS or within the areas of potential impact. All data on existing conditions within LANL boundaries, including policy, procedural issues, and existing resources, were obtained for 1995 conditions. It is assumed that both policies and known resources are constantly changing within a facility as large as LANL. One area of cultural resource management, in particular, has been undergoing rapid change at LANL: the development of new contacts among LANL and the various American Indian tribal governments.

E.6.1 Cultural Resource Management at LANL

Issues regarding cultural resources at LANL are handled by the LANL Cultural Resources Management Team (CRMT) of the Environmental Assessments and Resource Evaluations Group of the Environment, Safety, and Health Division at LANL.

In a memorandum from the Director of the Environmental Guidance Division, DOE Headquarters, dated February 23, 1990, DOE was directed to ensure that management of cultural resources at all DOE facilities is in compliance with all cultural resource executive orders, laws, and regulations. The memo further stipulates that DOE programs must budget sufficient funds to support cultural resource compliance actions and programs. The CRMT follows the LANL compliance procedure outlined in the LANL *Cultural Resource*

TABLE E.5.4–1.—*Potential Impacts of Actions on Prehistoric Resource Types*

ACTION TYPE	PUEBLO STRUCTURES	ERODED PUEBLOS/ RUBBLE/ ARTIFACT SCATTER	CAVATE PUEBLOS/ROCK ART/SHELTERS AND OVERHANGS	TRAILS/STEPS/ ROCK RINGS OR STONE ARRANGEMENTS
New Construction (direct)	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites
Increased Vibrations (from traffic, explosive testing, etc.	Destruction/alteration Damage to sites	None	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites
Increased Erosion or Siltation	Destruction/alteration Damage to sites	Destruction/alteration Damage to sites	Destruction/alteration Damage to sites	Destruction/alteration Damage to sites
Shrapnel Scatter from Firing Points	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions
Explosives (direct hits)	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites	Destruction/alteration Removal of or damage to sites
Radiation Hazards (from airborne or waterborne contamination)	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions
Noise	None	None	None	None
Hazardous Material (nonradiological from airborne or waterborne contamination)	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions	Isolation/restriction of access Inability to access sites because of hazardous conditions
Reduced Security	Destruction/neglect, alteration Removal of or damage to sites Deterioration and damage to sites from vandalism	Destruction/neglect, alteration Removal of or damage to sites Deterioration and damage to sites from vandalism	Destruction/neglect, alteration Removal of or damage to sites Deterioration and damage to sites from vandalism	Destruction/neglect, alteration Removal of or damage to sites Deterioration and damage to sites from vandalism

Note: For archaeological sites that are also TCPs, refer to Table E.5.4–3.

TABLE E.5.4–2.—*Potential Impacts of Actions on Historic Resource Categories*

ACTION TYPE	U.S. TERRITORIAL AND HOMESTEAD SITES	NUCLEAR ENERGY PERIOD BUILDINGS, DISTRICTS AND SITES (1943 TO 1989)			
		ADMINISTRATION BUILDINGS	STORAGE AND SERVICE	LABORATORIES AND PRODUCTION	HOUSING AND OTHER
New Construction (direct or indirect)	Destruction/ alteration Removal of or damage to sites Introduction of elements out of character with setting	Destruction/ alteration Removal of or damage to sites Introduction of elements out of character with setting	Destruction/ alteration Removal of or damage to sites Introduction of elements out of character with setting	Destruction/ alteration Removal of or damage to sites Introduction of elements out of character with setting	Destruction/ alteration Removal of or damage to sites Introduction of elements out of character with setting

Overview and Data Inventory 1995. The procedure was designed to keep LANL in compliance with the NHPA of 1966, as amended (16 U.S.C. §470); the *Archaeological Resource Protection Act* (ARPA) of 1979; AIRFA of 1978 (42 U.S.C. §1996); Executive Order 13007, Section 2(b); NAGPRA of 1990 (25 U.S.C. §3001); NEPA (42 U.S.C. §4321); and DOE's American Indian Policy (DOE Order 1230.2).

According to the LANL compliance procedure, the CRMT follows a step-by-step process to evaluate LANL actions for cultural resource compliance.

- The CRMT reviews all proposed LANL actions to determine if they are undertakings as defined in 36 CFR Part 800. According to the LANL compliance procedure, "Undertakings are activities that have the potential to affect a cultural resource and are typically activities outside buildings that disturb the ground" (LANL 1995c).
- Once an action is determined to be an undertaking, the CRMT conducts surveys of the affected area to determine if eligible cultural resources are likely to be affected by the proposed action. Cultural resource surveys are LANL controlled-release documents that are sent to the SHPO for concurrence with findings and for making determinations of eligibility. The surveys are also sent to the governors of the four Accord tribes (San Ildefonso, Santa Clara, Jemez, and Cochiti) for comment and identification of TCPs in the affected area.
- If both the DOE and the SHPO agree that a particular undertaking will have an adverse affect on eligible cultural resources, the CRMT develops a mitigation plan, specifying how the adverse effect will be mitigated. The mitigation plan is reviewed and approved by the SHPO and the National Advisory Council on Historic Preservation. According to the LANL compliance procedure, input from the public and interested American Indian groups is also solicited.
- Implementation of the mitigation plan may involve excavation of prehistoric sites if they are eligible for the NRHP under Criterion D alone. Data are analyzed by the CRMT as specified by the mitigation plan, and all recovered artifacts are curated at the Museum of New Mexico in Santa Fe, New Mexico.

In addition to the steps outlined above, measures are taken by the CRMT to provide American Indian tribes with access to information and input to the process of cultural resource management. Monthly meetings are held among DOE, the CRMT, LANL's legal counsel, LANL's Government Relations Office, and representatives of the four Accord tribes: San Ildefonso, Santa Clara, Jemez, and Cochiti. At these meetings, tribal representatives are advised of projects that may have impacts to cultural resources. According to the LANL compliance procedure, "...their input is invited on all phases of cultural resource survey, report preparation, determination of effects to cultural resources, and design of mitigation measures" (LANL 1995c). Any other tribes that identify themselves to LANL as having cultural affiliation with the region may also take part in these meetings or may be notified of LANL actions and included in consultations (Oakes 1997).

For purposes of compliance with NAGPRA, since 1995 the CRMT policy has been to contact local pueblo groups believed to be culturally affiliated with prehistoric sites at LANL, whenever human remains are uncovered. These pueblo groups would be asked for direction in the treatment and disposition of human remains.

The CRMT maintains a cultural resource administrative paper database and an electronic database and GIS of archaeological survey data. Administrative and compliance data are maintained on paper and electronically. These data include project review information, cultural resource survey data, and data on any subsequent reports. Archaeological data files include location data, site type, age, cultural affiliation, survey information, TA numbers, eligibility information, and any associated report numbers. As of 1995, the electronic prehistoric database did not contain data on the age or cultural affiliation of archaeological resources at LANL; however, these data could be found in the CRMT's paper database.

A separate electronic database has been maintained for historic resources at LANL from the Nuclear Energy Period (post-1942). This database is organized by LANL facility number and includes information about building or structure type, location, construction date, and current status or use. Some data have been added in 1995 from surveys that were conducted prior to demolition of a number of structures from this period. Comprehensive surveys have not been conducted to identify Nuclear Energy Period resources, including those from the World War II/Early Nuclear Weapons Development Period at LANL.

An archaeological site number is assigned to each new archaeological site that is encountered at LANL and a site form is filled out for most, but not all sites (LANL 1995c). Data included on the site forms have changed over the years, producing inconsistencies in the database. Beginning in 1995, the state's standard site form (used in the New Mexico Cultural Resource Information System) has been used by the CRMT. Prior to 1978, data on the site type and the age of the site were not consistently included on site forms used at LANL (PC 1995 and LANL 1995c). Site forms should be submitted to the SHPO for inclusion in the state database and the New Mexico Historic Preservation Division's ARMS. Some submittals to the SHPO are several years behind (PC 1995).

As a result of differences in information recorded on site forms at LANL and delays in the submittal of site forms to the SHPO, discrepancies exist between the state site records and LANL records.

E.6.2 Prehistoric Resources Within LANL Boundaries

A total of 1,302 prehistoric archaeological sites (sites with unique Laboratory of Anthropology numbers) have been identified within or very near LANL boundaries during archaeological investigations (LANL 1995c). The areas being considered in the SWEIS contain 1,295 sites, according to GIS overlay analysis. A breakdown of archaeological site types is provided in Table E.6.2–1. The site types have been grouped in this table according to the manner in which they respond to various impacts, such as vibration, erosion, corrosion, or explosions.

Eligibility assessments have been made on 1,192 prehistoric sites, with 770 sites found to be eligible for inclusion in the NRHP. There are 322 sites that are potentially eligible, and only 100 sites have been determined ineligible for nomination to the NRHP. The remaining 103

TABLE E.6.2–1.—*Prehistoric Cultural Resource Sites Within LANL Boundaries*

SITE TYPE	NUMBER OF SITES
Simple Pueblos	665
Complex Pueblos	62
Rock Shelters, Cavate (small caves) Pueblos	213
Rock Art	40
Water Control Features, Game Traps	56
Trails, Steps	20
Highly Eroded Pueblos, Rubble	29
Artifact Scatter, Stone Chips (lithic scatter), Rock Rings	210
TOTAL	1,295

Source: LANL 1995c

sites have not been assessed for eligibility, but are assumed to be potentially eligible by the LANL CRMT until further assessment is completed (PC 1995).

Archaeological survey work has been extensive at LANL. Several hundred small, project-related archaeological surveys have been conducted since the implementation of the NHPA at LANL in the early 1970's (LANL 1995c). Only 25 percent of LANL remains completely unsurveyed (LANL 1995c). Many LANL areas have been surveyed for archaeological resources at 100 percent coverage; others have been surveyed with only 60 percent coverage.

E.6.3 Historic Cultural Resources Within LANL Boundaries

A total of 2,319 cultural resources date from the Historic Period. There are 87 known cultural resources within LANL boundaries that date from the Early U.S. Territorial/Statehood Period, as shown in Table E.6.3–1. Most of these cultural resources have been recorded and their eligibility has been established in some cases. Of the 87 homestead resources, 22 are eligible for the NRHP. One site is also listed on the State Register of Cultural Properties. Three of these sites have been excavated (LANL 1995c).

Most cultural resources attributed to the Historic Period date from the Nuclear Energy Period, beginning with World War II and continuing through the end of the Cold War in 1989. However, no systematic survey has been conducted of the Historic Period cultural resources within LANL boundaries, nor have these resources been uniformly evaluated for eligibility for nomination to the NRHP.

Historic data about resources constructed at LANL during the World War II and the Cold War Periods have been obtained for purposes of the SWEIS from the LANL report, *Capital Asset Management Process, Fiscal Year 1997* (LANL 1995a). These data do not include non-building remains of those periods, and the numerous interrelated infrastructure support systems and functional systems present at LANL are not fully identified (LANL 1995c). The LANL Cultural Resources Database of potential historic facilities includes many existing and demolished structures.

A search of available data indicates that about 2,232 buildings, structures, or trailers that date from the Nuclear Energy Period existed at LANL in 1995. Analysis of the data shows that about 515 resources date from 1943 through 1956, and 1,717 date from 1957 through 1989. These numbers are approximate because nonbuilding resources have not been identified and demolition actions are ongoing.

E.6.4 Traditional Cultural Properties in the LANL Region

Within LANL's limited access boundaries, there are ancestral villages, shrines, petroglyphs, sacred springs, trails, and traditional use areas that could be identified by Pueblo and Athabascan communities as TCPs. The LANL CRMT has a program in place to manage on-site cultural resources for compliance with NAGPRA and AIRFA (LANL 1995c). The Pueblos of San Ildefonso and Santa Clara are considered to be most directly affiliated with archaeological sites at LANL (PC 1995 and Oakes 1997). When there is an undertaking, LANL arranges site visits by tribal representatives of the four Accord Pueblos to solicit their concerns and to comply with applicable requirements and agreements. However, this notification has been limited to Section 106 and NAGPRA compliance. Until recently, there has never been a systematic study of the TCPs at LANL that would identify other communities with potential concerns. Furthermore, TCPs that are natural features, resource gathering places, or hunting areas,

TABLE E.6.3–1.—*Historic Sites Identified by the SWEIS*

HISTORIC PERIOD	DATES	CHARACTERISTIC CULTURAL EVIDENCE	NUMBER OF KNOWN ARTIFACTS OR SITES	NATIONAL REGISTER OF HISTORIC PLACES ELIGIBILITY
Spanish Colonial	A.D. 1600 to 1849	• Wagons • Iron hardware • Horse equipment • Pueblo V artifacts	0	
Early U.S. Territorial/ Statehood	A.D. 1850 to 1942	• European and Hispanic homesteads • Commercial ranching concerns/guest ranches: Pond cabin, Anchor Ranch, and the Los Alamos Ranch School	87	Twenty-two sites are eligible for the NRHP. One site is also listed on the State Register of Cultural Properties.[a]
Nuclear Energy	A.D. 1943 to present			
a. World War II/ Early Nuclear Weapon Development Period	A.D. 1943 through 1948	• Original Los Alamos townsite • World War II Manhattan Project facilities where the design and manufacture of the "Trinity Site: bomb; Hiroshima bomb, "Little Boy;" and Nagasaki bomb, "Fat Man" occurred • LANL sites where all U.S. Nuclear Weapons were made from 1946 to 1950 • Common artifacts consist of buildings, security fences and stations, barricades, roads, reinforced protective structures	515 (1943 to 1956)	Seventy-seven sites are eligible for the NRHP (1943–1956). One is also listed on the State Register of Cultural Properties.[a]
b. Early Cold War Period	A.D. 1949 through 1956	Pronounced expansion of facilities		
c. Late Cold War Period	A.D. 1957 through 1989	Continued expansion of facilities	1,717	These LANL buildings have not been assessed for NRHP eligibility.
Total Number of Sites			2,319	

Sources: LANL 1995–1996, LANL 1995b, LANL 1995c, McGehee 1995, and NMHPD 1995.
[a] The Ashley Pond cabin is listed twice because its occupation and use spans two historic periods.

have neither been identified nor considered in the evaluation of effects from LANL undertakings.

According to the LANL compliance procedure, American Indian tribes may request permission for visits to sacred sites within LANL boundaries for ceremonies (Oakes 1997). However, the procedure takes time, and no instances were found to indicate that tribes access ceremonial or other traditional sites by this means.

American Indian TCPs, located on lands outside LANL boundaries, such as tribal lands, state lands, federally managed lands, and private lands, may be potentially affected by LANL activities. Other federal agencies with land holdings in the area that may have TCPs include:

- U.S. Forest Service, Santa Fe and Carson National Forests
- NPS, BNM
- DOI, Bureau of Land Management, Taos Resource Area

Consultations were held with 19 American Indian tribes and two Hispanic communities as part of the SWEIS TCP study. Several contacts were made with 23 American Indian tribes; however, four did not participate in the consultations. Of the contacted communities, only the Pueblo of Santa Ana did not wish to participate at this time. The Pueblo of San Felipe showed interest during repeated telephone contacts and presentations; however, they did not elect to hold consultations during the SWEIS TCP study. All of the consulting groups indicated that they had at least some TCPs present on or near LANL, as summarized in Table E.6.4–1. These resources are present throughout LANL and adjacent lands, including the neighboring BNM, reservation lands, Santa Fe National Forest and U.S. Forest Service land.

The following subsections outline the results of consultations with American Indian and Hispanic communities. These subsections comprise statements made during the consultations, classified by the following categories: ceremonial and archaeological sites, natural features, ethnobotanical gathering sites, artisan material gathering sites, and subsistence features.

E.6.4.1 *Ceremonial Sites*

- *Pueblo of Acoma*—Pueblo of Acoma officials do not claim cultural affiliation to sites in the LANL area except in a general sense as Pueblo people. They do, however, have concerns about the treatment of human remains that may exist in the LANL area. In addition, all archaeological sites in the area are considered sacred to all Pueblo people.
- *Pueblo of Cochiti*—Tribal representatives stated that LANL is part of their ancestral domain.
- *Pueblo of Jemez*—Although LANL is on the periphery of the ancestral Jemez

TABLE E.6.4–1.—*Traditional Cultural Properties Identified by Consulting Communities on or near LANL Property*

	CEREMONIAL AND ARCHAEOLOGICAL SITES	NATURAL FEATURES	ETHNO-BOTANICAL SITES	ARTISAN MATERIAL SITES	SUBSISTENCE FEATURES
Number of Consultations Indicating the Presence of TCPs on or near LANL	15	14	10	7	8

domain, since the days of prehistory, the Jemez people have continued to make pilgrimages to sacred sites in the vicinity of Los Alamos. The Jemez people have shrines in the Los Alamos area, but not in the LANL compound.

- *Pueblo of Laguna*—Representatives from the Pueblo of Laguna indicated that the LANL area is part of Laguna's traditional use area and BNM is an important area to the tribe.
- *Mescalero Apache Tribe*—Tribal representatives stated that at least three ceremonial feast areas are located in the LANL area.
- *Navajo Nation*—Navajo tribal records document that the LANL area is a very old traditional use area with at least 20 ceremonial/archaeological sites in the area.
- *Pueblo of Picuris*—Representatives from the Pueblo of Picuris stated that their people have cultural affiliation with archaeological sites near and at LANL.
- *Pueblo of Pojoaque*—A representative from the Pueblo of Pojoaque stated that the Pueblo has traditional sites in the LANL area. Tribal members mostly travel to the east to hold ceremonies but go in all directions for prayers; e.g., towards Santa Fe and White Rock. Many tribal members long ago went to the Los Alamos area, traveling through San Ildefonso and Garcia Canyon to White Rock. Oral stories often pertain to Jacona Peak and the BNM area. A traditional trail traverses what is now LANL, but it is no longer used due to denied access.
- *Pueblo of Sandia*—Tribal officials from the Pueblo of Sandia said that archaeological sites in the LANL area are important. Sandia is concerned over the treatment of human remains. "They should be left alone," according to tribal representatives.
- *Pueblo of San Ildefonso*—The Pueblo of San Ildefonso recognizes the Los Alamos area as its ancestral domain. San Ildefonso claims to have over 1,500 TCPs within LANL boundaries.
- *Pueblo of Santo Domingo*—Officials from the Pueblo of Santo Domingo said tribal members use springs in the high country for ceremonial purposes, and they are concerned about pollution at these springs.
- *Pueblo of Taos*—Tribal representatives stated that tribal members travel to areas near LANL for ceremonial functions; and that, although they no longer conduct traditional activities in the immediate area of LANL, it is still considered to be sacred to them.
- *Pueblo of Zia*—Traditional routes to buffalo hunting areas in Colorado traverse LANL, along the Cuba Road and up the Rio Grande. Another route goes along the base of the Pajarito Plateau, east of LANL. These routes contain many shrines and many of these shrines are recounted in oral stories. There are also many archaeological sites, shrines, and springs in the LANL area that are important to the Zia people.
- *Pueblo of Zuni*—Representatives from the Pueblo of Zuni stated that they are concerned about the archaeological sites in the region; e.g, the Stone Lions at BNM. Prehistoric pottery affiliated with the Zuni people has been found at LANL.
- *Hispanic Communities*—Hispanic communities identified several ceremonial sites, such as traditional pilgrimage route that leads from the Jemez Springs area, through LANL, and along the highway to the Santuario de Chimayo. Another pilgrimage route exists between Wagon Mound and the Santuario de Chimayo. Pilgrimages are conducted on foot both at Christmas and during Lenten week. A third pilgrimage or procession area exists along Highway 84 near Abiquiu. Many pilgrimage trails converge on the Santuario de Chimayo in the Nambe area. Some representatives mentioned that privatization of some land had limited access to pilgrimage trails and sacred sites.

Descansos, crosses or stone markers along pilgrimage routes are used as sites to remember the dead. Ceremonies are also conducted along the acequias in some villages to protect the water and ensure good crops, according to Hispanic consultants.

E.6.4.2 *Natural Features*

- *Pueblo of Acoma*—Officials from the Pueblo of Acoma stated that the LANL area is sacred.
- *Hopi Tribe*—Hopi tribal representatives stated they hold the Jemez Mountains as traditionally significant, and Hopi Kachinas go to their home in these mountains.
- *Jicarilla Apache Tribe*—The Jemez Mountains were identified by the Jicarilla Apache Tribe as culturally significant. They have traditionally bathed in hot springs in various locations, including the Jemez area and Pagosa Springs.
- *Mescalero Apache Tribe*—The Mescalero Apache tribal officials indicated that Los Alamos Mountain is of traditional importance.
- *Navajo Nation*—Tribal documents of the Navajo Nation identify 19 natural features in the LANL area. The Jemez Mountains are significant and Pajarito Mountain and Pajarito Springs are considered sacred. Pajarito Mountain is tied to the Navajo creation story.
- *Pueblo of Picuris*—Tribal members of the Pueblo of Picuris have traditionally used the hot springs at Jemez.
- *Pueblo of Pojoaque*—Oral stories from the Pueblo of Pojoaque pertain to Jacoma Peak and BNM.
- *Pueblo of Sandia*—Springs in and around LANL are important to members of Sandia Pueblo. They consider all springs as shrines, sacred places for prayer.
- *Pueblo of San Juan*—Representatives from the Pueblo of San Juan stated that among the significant resources in the LANL area, Jacona Peak is one of the most important.
- *Pueblo of Santa Clara*—Tribal officials from the Pueblo of Santa Clara stated that the entire Pajarito Plateau is significant not only to Santa Clara but to all the Pueblos.
- *Zia Pueblo*—One of the important features to the Zia people is Santa Clara Peak.
- *Pueblo of Zuni*—Representatives from the Pueblo of Zuni said the LANL area is part of their traditional use area and tribal members collect water in the vicinity. They are concerned about the effects of LANL activities on springs.
- *Hispanic Communities*—Natural features were not mentioned as important Hispanic TCPs in any consultations.

E.6.4.3 *Ethnobotanical Gathering Sites*

- *Hopi Tribe*—Members of the Hopi Tribe gather cattails from the LANL area for dances.
- *Pueblo of Jemez*—The Jemez people have traditionally collected and continue to collect medicinal plants and other plants in the Los Alamos vicinity.
- *Jicarilla Apache Tribe*—Members of the Jicarilla Apache tribe collect willow, sumac, and medicinal plants in the LANL area.
- *Mescalero Apache Tribe*—Members of the Mescalero Apache tribe have plant gathering areas near LANL.
- *Pueblo of Nambe*—Officials from the Pueblo of Nambe stated that the Los Alamos area is a Nambe traditional use area and the people from the Pueblo gather plants in the vicinity.
- *Pueblo of Pojoaque*—Pojoaque tribal members go towards Santa Fe and White Rock for pinyon nut gathering and plant gathering.

- *The Pueblo of Sandia*—Tribal officials cannot give specific plant collection locations because weather patterns change and collection locations change annually with weather patterns. They collect wild tobacco, prickly pear, yucca root, gooseberries, chokecherries, osha, wild spinach, bee weed (for paint), wild garlic, and juniper roots from the Jemez Mountains and around Fenton Lake, as well as pinyon nuts and evergreens from the Jemez Mountains.
- *Pueblo of Zia*—Many herbs are collected by members of Zia Pueblo in the canyons around LANL, such as Pueblo Canyon.
- *Pueblo of Zuni*—Representatives of the Pueblo of Zuni said tribal members collect plants in the LANL vicinity.
- *Hispanic Communities*—Many wild plants are gathered for medicine and food by traditional Hispanic people in the LANL region. The Jemez Mountains were mentioned during the consultations as an important area for gathering pinyon nuts, wild fruit, and herbs. The areas where herbs are picked vary according to season and year. Some of the medicinal plants that are gathered in the LANL region include cota, osha, yerba buena, and chimaha. Participants mentioned that families and groups make outings to the mountains to gather plants. Barranca Mesa, north of LANL boundaries, and Ojo Caliente were identified as important areas to gather wild plants.

E.6.4.4 *Artisan Material Gathering Sites*

- *Pueblo of Jemez*—The Jemez people collect obsidian and other minerals from the area.
- *Jicarilla Apache Tribe*—Members of the Jicarilla Apache tribe collect clay, pigment, and plants for basketry in the LANL area, including the Jemez Mountains, the Santa Clara and Taos areas, and the Sangre de Cristo Mountains. Micaceous clay is collected in numerous places including the El Rito area.
- *Pueblo of Nambe*—Members of the Pueblo of Nambe gather minerals in the vicinity.
- *Navajo Nation*—Navajo tribal records document four resource gathering areas in the LANL area.
- *Pueblo of Picuris*—Tribal members of the Pueblo of Picuris have collected chert near Cochiti, and their ancestors collected obsidian in the LANL area.
- *Pueblo of Taos*—Tribal members collect clay and wood from the Santa Clara and San Juan areas.
- *Pueblo of Zia*—Obsidian is collected at Obsidian Ridge by tribal members of Zia Pueblo.
- *Hispanic Communities*—Members of the Hispanic communities mentioned wood for vigas and latillas, wood for carving, and plants to dye wool, as materials commonly gathered from the areas around LANL. Some dye plants such as goldenrod are gathered along acequias. Other plants are gathered along roadsides (chamisa and cota) or in the foothills (Mormon tea). Wood for carving Santos is collected in the Los Alamos area, including cottonwood and aspen from the Santa Fe National Forest. Juniper is gathered in bulk by families for carving. Santa Clara, El Rito, the Tecolote area near La Madera, and Dixon were mentioned as areas where clay is gathered. Micaceous clay is gathered at Petaca. Special crystals called Lagrimas de Dios are collected near Dixon by artisans. One consultant mentioned that she had formerly gathered ephedra and other plants to dye her wool along the roads around LANL, but had discontinued the practice because she believed the plants were contaminated.

E.6.4.5 *Traditional Subsistence Features*

- *Pueblo of Jemez*—The Jemez people collect water from ancient springs in the area and hunt deer and elk that have migrated into the ancestral Jemez domain from the LANL area.
- *Jicarilla Apache Tribe*—Members of the Jicarilla Apache Tribe hunt in the LANL area, and some of their livestock graze near the southern border of the Jicarilla Apache reservation.
- *Pueblo of Nambe*—Officials from the Pueblo of Nambe stated that the Los Alamos area is a Nambe traditional use area and the Pueblo has TCPs located within the vicinity. Many traditional, ceremonial, and culturally used products are gathered within the area that they feel may be affected by current and future LANL undertakings. The Pueblo of Nambe people use the Los Alamos area for hunting, fishing, and wood gathering. In addition, tribal members farm, raise crops, provide feed for livestock, and gather plants and minerals in the vicinity.
- *Navajo Nation*—Tribal documents of the Navajo Nation identified two trade centers in the LANL area.
- *Pueblo of Pojoaque*—Many tribal members from the Pueblo of Pojoaque went to the Los Alamos area long ago, traveling through San Ildefonso and Garcia Canyon to White Rock, and many still hunt in this vicinity.
- *Pueblo of Sandia*—Members of the Pueblo of Sandia hunt deer and elk in the Jemez Mountains and north to the Colorado Border. They fish in the Santa Clara and Jemez areas, Santa Cruz Lake, and at Nambe Falls.
- *Pueblo of Taos*—Tribal members use the Rio Pueblo and the Rio Grande for collection of water.
- *Pueblo of Zia*—Activities that historically have taken place in Pueblo Canyon include animal collection using deer traps. Tribal members consider these deer traps to be traditional properties. The area around LANL was a prime hunting area.
- *Hispanic Communities*—Protection of the water rights and water quality of the acequias are very important to traditional Hispanic communities. Rituals are performed in the springtime to bless the water, along with the annual cleaning of the acequias. This was mentioned by several informants as very important to the community. One informant said that this was the way her children learned about the ways of the people, by working together to keep the ditch clean and to allocate the water.

Hunting and fishing were mentioned by Hispanic informants as being important traditional subsistence activities that bring together families. Outings into the mountains to hunt also include gathering pinyon nuts and fruit or firewood and involve several family members. Informants mentioned that their families used to hunt in the LANL area, but now are prevented by LANL fences and private land. People in Jemez Springs said that hunting and fishing is important to their local traditions. Wild meat is a staple of their diet in many families, and teaching one’s children to provide their own meat and jerky was mentioned as an important tradition. A participant described hunting for deer in Guaje Canyon and wild turkey around Barranca Mesa many years ago, but he no longer has access to these areas.

APPENDIX F
TRANSPORTATION RISK ANALYSIS

F.1 INTRODUCTION

Following in this appendix are more detailed descriptions of the transportation risk analysis methodology and results that are summarized in the main volume of the SWEIS.

Section F.2 includes a description of the types of radioactive material (RAM) packaging required by the regulations of the U.S. Department of Transportation (DOT), the U.S. Nuclear Regulatory Commission (NRC), and DOE, and examples of how packaging is used at LANL. Containers for hazardous materials (HAZMAT) are also described in section F.2. Risk measures are described in section F.3.

The methodology for quantifying the risk measures is described in section F.4. The methodology incorporates truck accident data with an emphasis on routes between Interstate 25 (I–25) and the LANL site; a computer program to determine routes, mileages, and associated population densities; and other computer codes to quantify incident-free exposures and accident doses.

The methodology for determining the numbers and types of shipments for the baseline and the identified SWEIS alternatives (No Action, Expanded Operations, Reduced Operations, and Greener) is described in section F.5.

The risk analysis results are presented in section F.6 for the base case and in section F.7 for the Santa Fe relief route case. To aid in understanding and interpreting the results, specific areas of uncertainty are described in section F.8, with emphasis on how the uncertainties may affect comparison of SWEIS alternatives.

F.1.1 Purpose of the Analysis

Although in DOT regulations (49 CFR 171.8) RAM is a subset of HAZMAT, for this transportation analysis they are addressed separately. The purpose of the transportation risk analysis is to address the human health risks arising from the transport of HAZMAT and RAM associated with the operation of LANL. The human health risks associated with truck traffic arise from exposure to the truck exhaust and the possibility of an accident that could produce injuries or fatalities. These two health risks are independent of the truck cargo and exist for similar shipments of any commodity.

The human health risks associated with the radioactive or hazardous cargo result from the possibility of release of the cargo in an accident. In addition, the radioactive cargo produces a radiation field external to the packaging even for normal conditions. Persons exposed to the external field receive a small level of radiation, referred to as incident-free exposure.

These health risks are characterized in terms of four risk measures: truck-related emissions, which could cause fatalities from latent cancer; fatalities and injuries due to collisions with heavy trucks; incident-free exposures to radiation, which could cause fatalities from latent cancer; and accidental releases of the radioactive or hazardous cargo, which could cause immediate or latent fatalities. These risk measures are described in section F.3, and the methodology used to quantify them is described in section F.4 of this appendix.

F.1.2 Scope of the Analysis

The scope of the analysis includes the transport of RAM or HAZMAT on public roads within the LANL site and off-site shipments of materials by truck or air. Air shipments begin and end with a truck shipment. Rail transport is not addressed in this analysis, because there is no rail service to LANL. The risks to workers or to the public from loading or unloading trucks prior to or after shipment are considered part of normal facility operations and are not addressed as part of the transportation analysis (these are addressed in the analysis of worker health risks due to radiation exposure in sections 5.2.6, 5.3.6, 5.4.6, and 5.5.6); however, handling during shipment is included. Shipments while public roads are temporarily closed are also included in this analysis.

The methods and assumptions described in this appendix were selected to ensure meaningful comparisons among the SWEIS alternatives. A number of generic assumptions appropriate to the overview nature of the SWEIS were made. For example, because a detailed analysis of every type of LANL shipment would be impractical, shipments representative of classes of materials were selected as described in section F.5. Three examples of material class are bulk solid RAM, liquid RAM, and flammable materials. Also, because the different packaging used for RAM are too numerous to analyze individually to determine how severe an accident must be to cause a release, all packaging meeting the same regulatory criteria are assumed to fail at the same accident force magnitude (and hence probability). These parameters are described in subsection F.4.4.

In DOT regulations on the transportation of RAM, packaging is defined in 49 CFR 173.403 as:

> ...the assembly of components necessary to ensure compliance with the packaging requirements of this subpart. It may consist of one or more receptacles, absorbent materials, spacing structures, thermal insulation, radiation shielding, and devices for cooling or absorbing mechanical shock.

A package is defined as "the packaging together with its radioactive contents as presented for transport."

The general rule used in this appendix is that all assumptions should be conservative enough to ensure that the results do not underestimate the level of transportation risk, but not so conservative that the risk calculation is knowingly orders of magnitude too conservative or the differences between alternatives are obscured.

The focus of the transportation accident analysis is on bounding accidents; i.e., the most severe, reasonably foreseeable accidents (DOE 1994a). Transportation accidents that may occur often but that do not involve major consequences are not addressed.

F.2 PACKAGING OVERVIEW

DOT is the lead federal agency for establishing and enforcing regulations regarding safe transportation of HAZMAT and RAM. Procedures to ensure safe packaging for HAZMAT and RAM include categorizing the material and requiring the use of a packaging or container appropriate to the category. In the case of RAM, the categorization is by form, quantity, and concentration of RAM. The premise underlying packaging design for most HAZMAT and RAM is that the packages must maintain their integrity in the normal transportation environment, which includes minor accidents. An exception is that highly RAM and their packaging must survive severe accident conditions without a dangerous release of contents. Because packaging represents the primary barrier between HAZMAT and RAM being transported and exposure of the public and the environment, the regulatory approach for ensuring safety is to specify standards for the packaging of HAZMAT and RAM. These packaging requirements are an important consideration for the transportation risk assessment, and typical packaging used at LANL are described in this section. Packaging and vehicles used for RAM are described first; then chlorine cylinders, propane cargo tanks, and explosives packaging are described.

DOT sets design and performance specifications for packaging that will carry up to Type A quantities of RAM. Under an agreement with DOT, NRC sets the standards for packages of Type A and Type B quantities of RAM (subsections F.2.3 and F.2.4). DOE meets NRC's standards for certain packages and follows DOT's regulations for shipping and packaging or provides equivalent protection for its shipments. Examples of general RAM packages are shown in Figure F.2–1.

F.2.1 Limited Quantity Packaging

Limited quantities are very small amounts of radioisotopes such as amounts found in smoke detectors, lantern mantles, watches, signs, and measuring devices. The level of radioactivity listed in 49 CFR 173.425 is so low that materials containing that level can be shipped without special packages, shipping papers, markings, and labeling requirements. The materials are packaged in accordance with the general design requirements of 49 CFR 173.410. Such packages must be designed for ease of handling and proper restraint during shipment. They must be free of protuberances, easily decontaminated, and capable of withstanding the effects of vibration during transport. All valves, through which the package contents could escape, must be protected (60 Federal Register [FR] [188] 50297).

F.2.2 Industrial Packaging

Industrial packaging (IP) are authorized as packaging for low-specific-activity (LSA) materials and surface-contaminated objects (SCOs). LSA materials are naturally occurring ores, concentrates, and other materials in which the activity is essentially uniformly distributed at low levels. In contrast, materials classified as SCO are not inherently radioactive; rather, they are objects with radioactive contamination on their surfaces, also at very low levels of activity. At a minimum, each IP must meet the general design requirements of 49 CFR 173.410: it must be designed for ease of handling and proper restraint during shipment; it must be free of protuberances, easily decontaminated, and capable of withstanding the effects of vibration during transport; and valves, through which the contents could escape, must be protected. These are the only requirements that apply to IP Type 1 (IP–1) (60 FR [188] 50297).

IP Type 2 (IP–2) must also survive the Type A free drop and stacking tests. Each IP Type 3 (IP–3) must meet the requirements for IP–1 and IP–2 and the following Type A package requirements (DOT 1995b):

- A seal must be incorporated on the outside of the packaging.
- Temperatures must be within a specified range.
- A containment system that is securely closed by a positive fastening device must be included.
- Any radiolytic decomposition of materials and generation of gas by chemical reaction and radiolysis must be taken into account.
- Radioactive contents must be retained under reduced pressure.
- Each valve (except a pressure-relief device) must have an enclosure to retain any leakage.
- Shielding must remain in place to protect the packaging components.
- The failure of any tie-down attachment must not impair the ability of the package to meet other requirements.
- No loss or dispersal of the radioactive contents or any significant increase in the

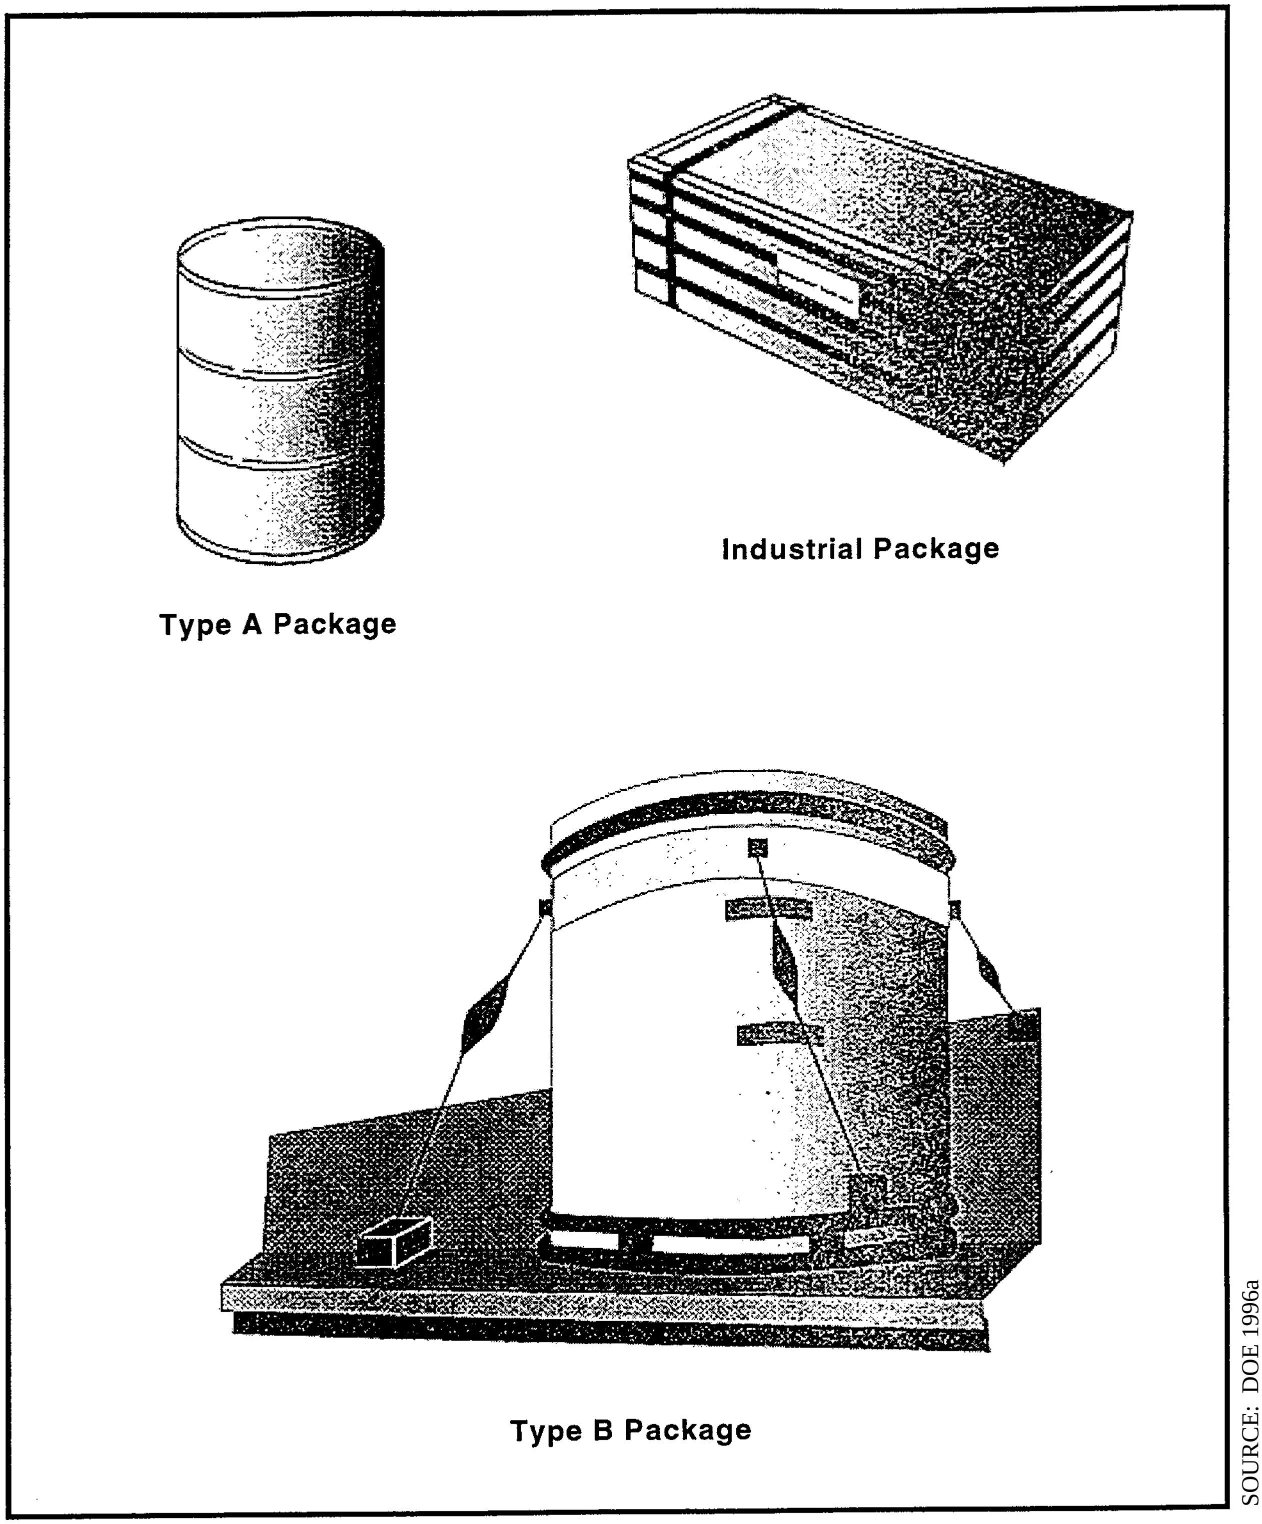

FIGURE F.2–1.—*Examples of Packaging Types.*

radiation levels at the external surfaces must occur when the IP–3 is evaluated against Type A packaging tests.

Solid depleted uranium is packaged in Type IP–1 packaging. Water with tritium concentrations up to 75.7 curies per gallon (20 curies per liter) is packaged in Type IP–2 packaging for exclusive-use shipments and Type IP–3 packaging for nonexclusive-use shipments. An exclusive-use shipment is one that is for the sole use of the consignor or consignee. SCOs such as decontamination and decommissioning wastes are packaged in Type IP–1 if the fixed alpha contamination is up to 6.45×10^{-7} curies per square inch (10^{-7} curies per square centimeter) and Type IP–2 if the fixed alpha contamination is up to 1.3×10^{-5} curies per square inch (2×10^{-6} curies per square centimeter) (60 FR [188] 50297).

F.2.3 Type A

Type A packaging are used for RAM with specific activities up to limits specified in the regulations. Type A packages must contain RAM under normal transportation conditions and must maintain sufficient shielding to limit exposure of handling personnel. Normal transportation refers to all transportation conditions except those resulting from major accidents or sabotage. Type A packages are generally steel drums or boxes made of steel, wood, or strong fiberboard (see Figure F.2.3–1 for an example of a Type A package). The packaging, with contents, must be capable of withstanding a series of tests (49 CFR 173.465) including: water spray, free drop (as high as 4 feet [1.2 meters], depending upon mass), compression, and penetration.

F.2.4 Type B

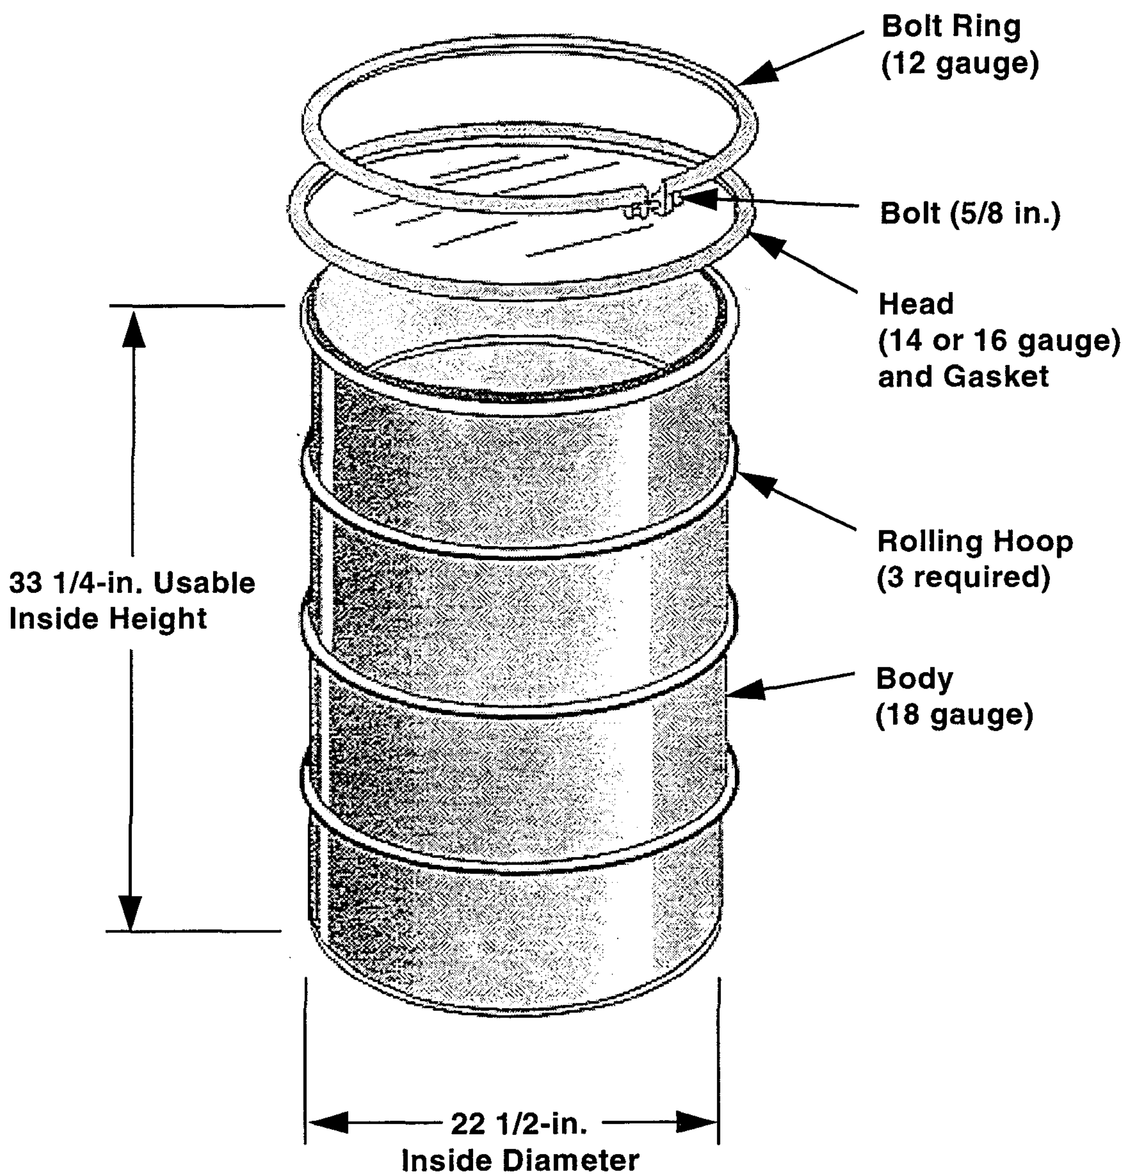
Type B containers are very durable packages used to contain and shield more hazardous amounts and forms of RAM than those contained in Type A packages. Type B packages are used to transport materials such as spent fuel and high-level radioactive waste that would present a radiation hazard to the public or the environment if a major release occurred. Type B packages must provide protection under both normal conditions of transport and severe accidents. The certified design and construction methods for Type B packages ensure the production of systems that will contain the packaged radioactive contents even after a series of rigorous accident tests. The tests for hypothetical accident conditions specified in 10 CFR 71.73 include free drop (30 feet [9 meters]), crush, puncture, thermal (exposure to 1,475°F [802°C] for 30 minutes), and immersion. The size of Type B packages can range from 40 pounds (18 kilograms) to over 100 tons (91 metric tons). Examples of Type B packages are presented in the following subsections.

F.2.4.1 *FL-Type Container*

The FL-Type container is currently the only certified container used for pit transport. It is a DOT Type B package with a 16-gage stainless steel outer containment drum surrounding a 12-gage stainless steel inner containment drum (Figure F.2.4.1–1). Fiberboard insulation is present between the inner and outer containment drums. Both the internal and external containment drums are constructed of stainless steel. The inner containment vessel is sealed with dual concentric silicone O-rings (DOE 1996c).

F.2.4.2 *Transuranic Packaging Transporter for Contact-Handled Transuranic Waste*

Contact-handled (CH) transuranic (TRU) waste is contaminated with man-made RAM with atomic numbers greater than uranium, such as plutonium, americium, and curium, which primarily emit alpha radiation. Because this type of radiation cannot penetrate human skin,



SOURCE: Cruse 1992

FIGURE F.2.3–1.—*Type A DOT–17H 55-Gallon (208-Liter) Steel Drum.*

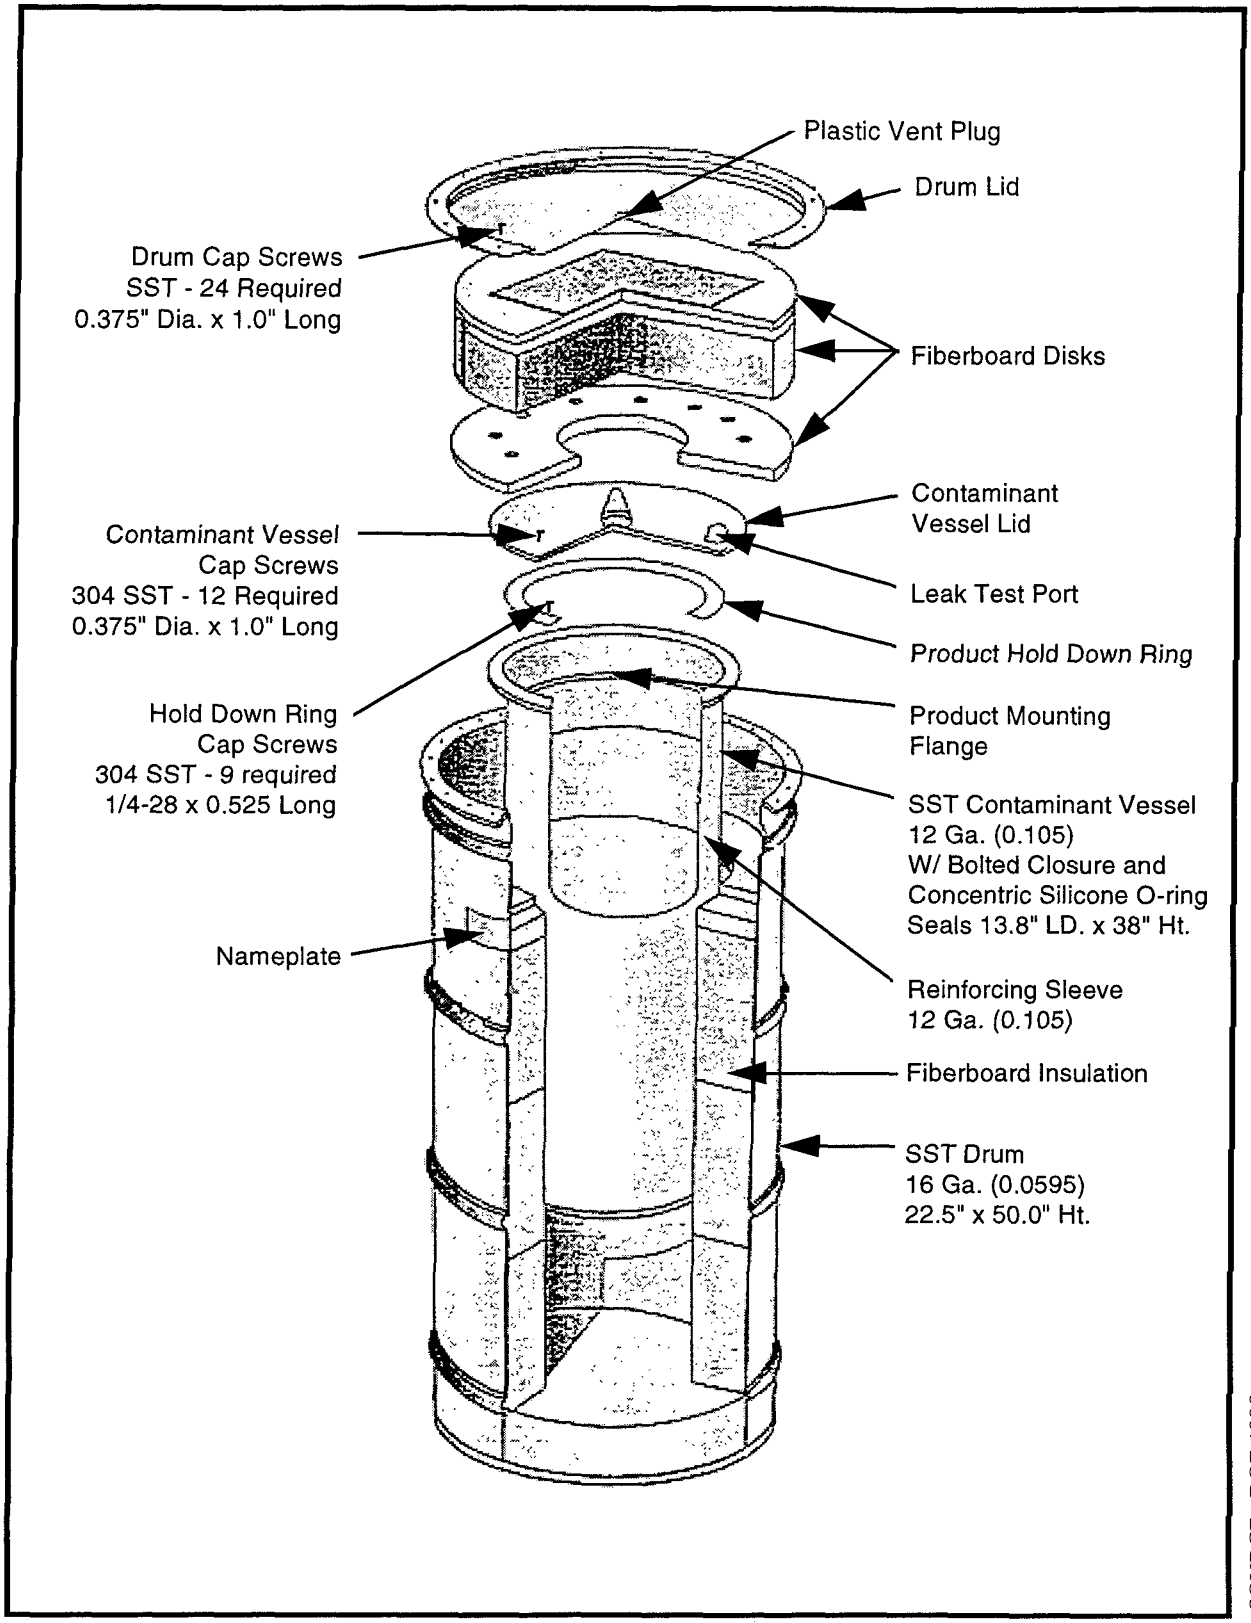


FIGURE F.2.4.1–1.—*Cross Section of an FL-Type Container.*

CH TRU waste is a hazard only if inhaled or ingested. The waste includes such materials as laboratory clothing, tools, glove boxes, plastic, rubber gloves, wood, metals, glassware, and solidified wastewater sludges contaminated with TRU materials. All CH TRU waste will be transported to the Waste Isolation Pilot Plant (WIPP) in the Transuranic Packaging Transporter (TRUPACT-II), a reusable shipping packaging. NRC certified this Type B package according to 10 CFR 71. As part of the certification process, full-scale TRUPACT-II prototypes were subjected to actual drop and fire tests to prove their ability to survive severe accident conditions.

The TRUPACT-II is a cylindrical metal container with a flat bottom and a domed top that is transported in an upright position (Figure F.2.4.2–1). Multi-layered wall design increases the package strength and provides the ability to withstand potential transportation incidents. The CH waste will be sealed in 55-gallon (208-liter) steel drums or waste boxes. Each TRUPACT-II can hold up to fourteen 55-gallon (208-liter) steel drums, or two standard waste boxes (WGA and DOE 1995).

F.2.4.3 *UC–609 for Tritium*

The UC–609 package consists of a containment vessel centered by fiberboard insulation inside a 100-gallon (379-liter) drum (Figure F.2.4.3–1). The tritium contents are carried in a storage vessel inside the containment vessel. The package gross weight is 500 pounds (227 kilograms). The drum is fabricated of 14-gage Type 304 stainless steel. The Type 316 stainless steel containment vessel is 18 inches (45 centimeters) in diameter and 44 inches (112 centimeters) long and is rated for service at 110 pounds per square inch (6.36 kilograms per square centimeter), gage (psig) at 293°F (145°C). To protect the storage vessel from the effects of an accident, the annular space between the storage vessel and the containment vessel wall is filled with aluminum honeycomb to absorb impact.

The allowable contents of the UC–609 is tritium in any form (except activated luminous paint) contained in a storage vessel. The maximum quantity of RAM per package is not more than 5.3 ounces (150 grams) of tritium with the decay heat not to exceed 48 watts. The oxygen content must be less than 5 percent by volume of the gas in the containment vessel. The maximum internal pressure of the containment vessel must not exceed 110 psig at 293°F (145°C) (Wangler 1995).

F.2.4.4 *DOT–6M*

The DOT–6M container is a metal packaging conforming to DOT Specification 6M (49 CFR 178.354). The sizes and payloads of DOT–6M containers vary. The rated capacity is not less than 10 gallons (38 liters) and no more than 110 gallons (416 liters) for the outer steel drum. The capacity of the inner containment vessel is not less than 0.33 gallon (1.24 liters). The inner containment vessel must conform to specification 2R or equivalent, with a maximum usable inside diameter of 5.25 inches (13.33 centimeters), a minimum usable inside diameter of 4 inches (10 centimeters), and a minimum height of 6 inches (15 centimeters). The inner containment vessel must be fixed within the outer shell by machined disks and rings made of solid industrial cane fiberboard, hardwood, or plywood. DOT Specification 6M metal packaging is used only for solid or gaseous RAM that will not undergo pressure-generating decomposition at temperatures up to 250°F (121°C) and that do not generate more than 10 watts of radioactive decay heat (49 CFR 173.416). A 55-gallon (208-liter) 6M packaging is shown in Figure F.2.4.4–1.

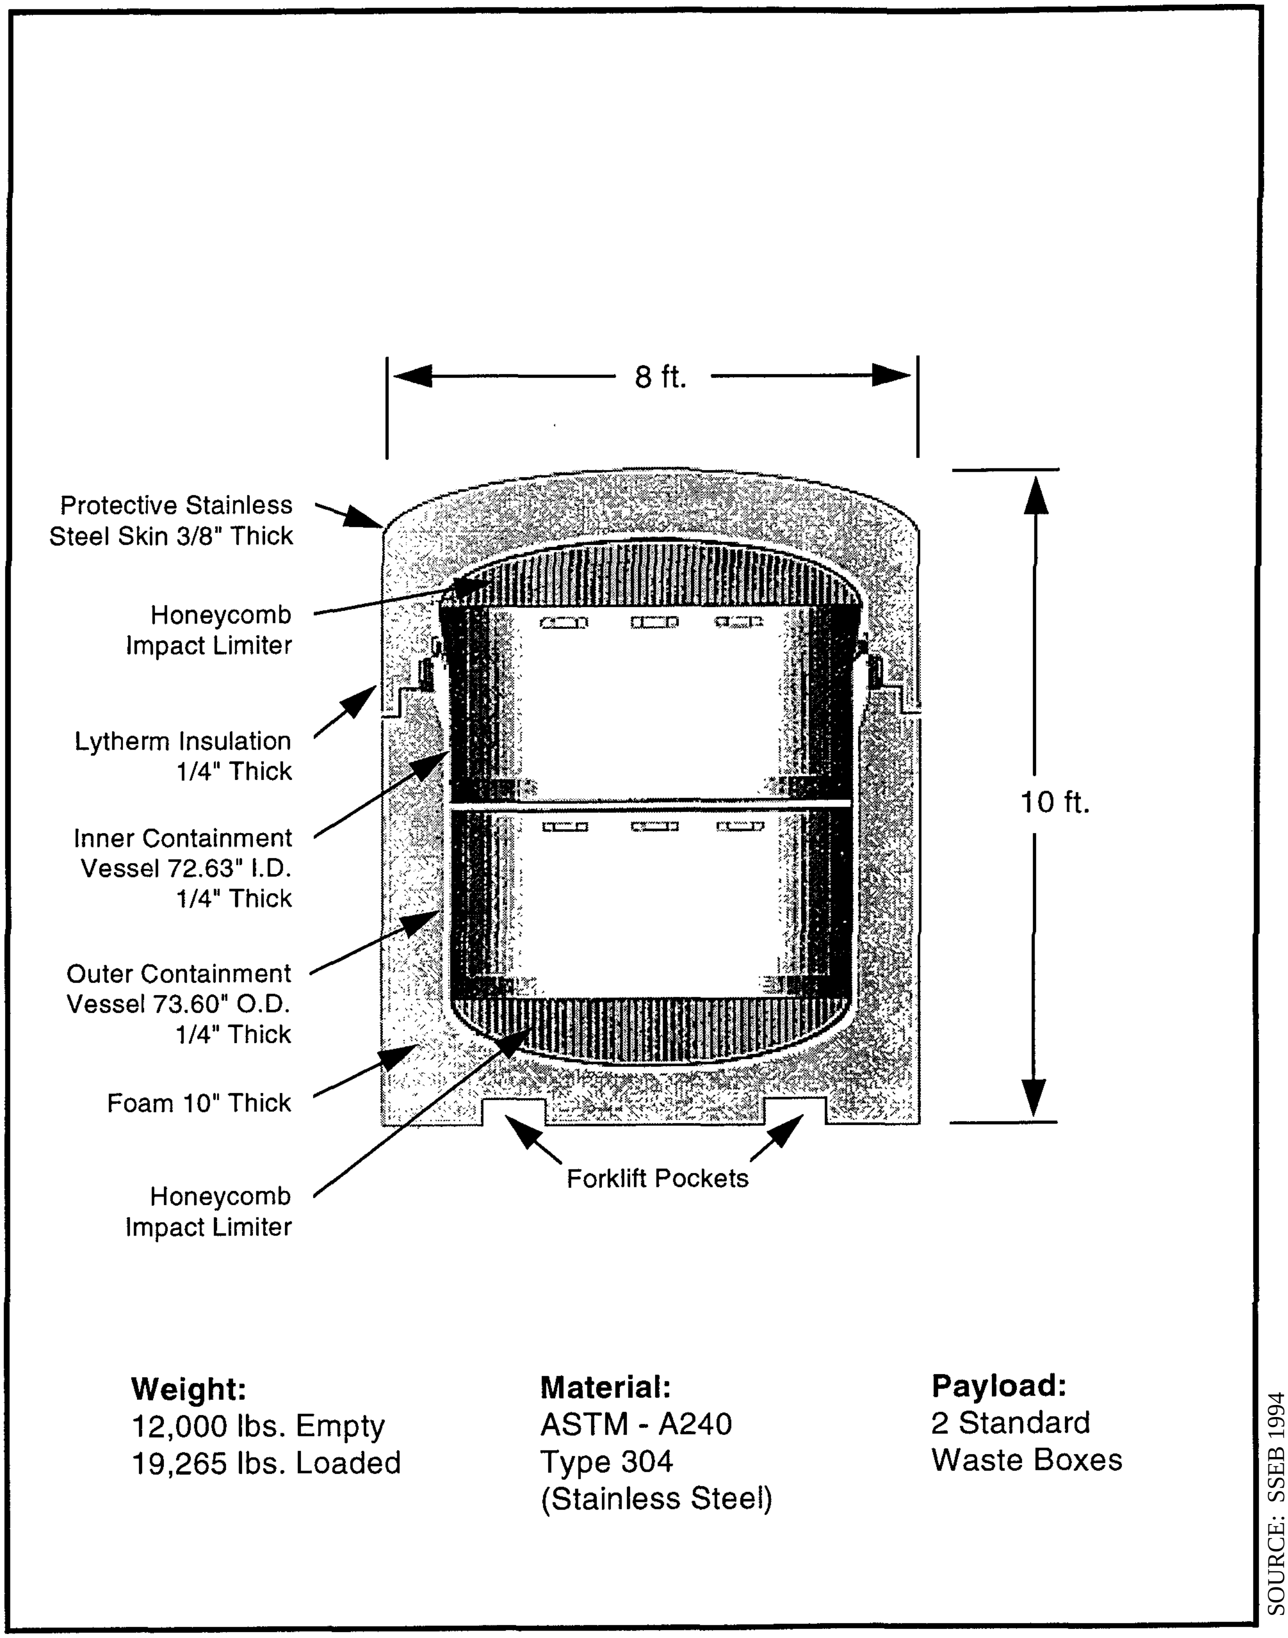

FIGURE F.2.4.2–1.—*TRUPACT-II.*

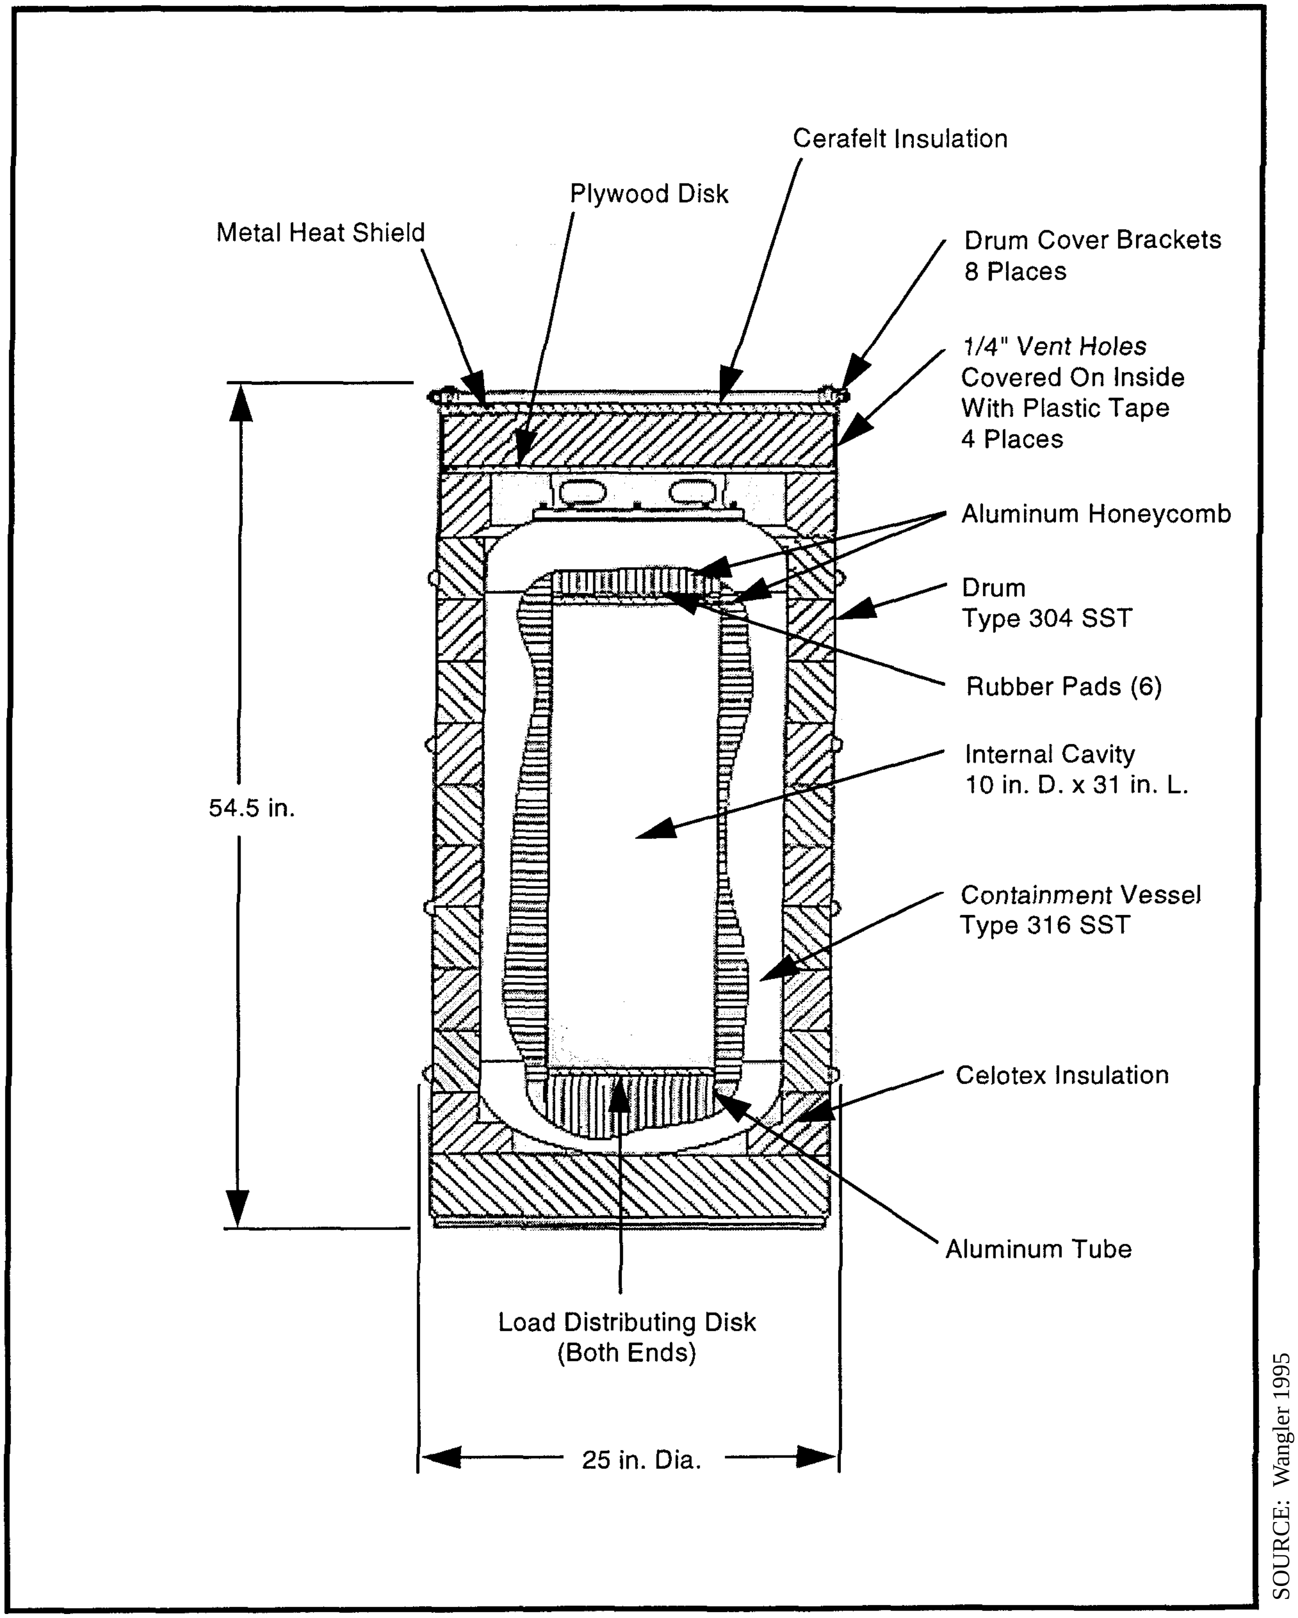

FIGURE F.2.4.3–1.—*Model No. UC–609 Shipping Package.*

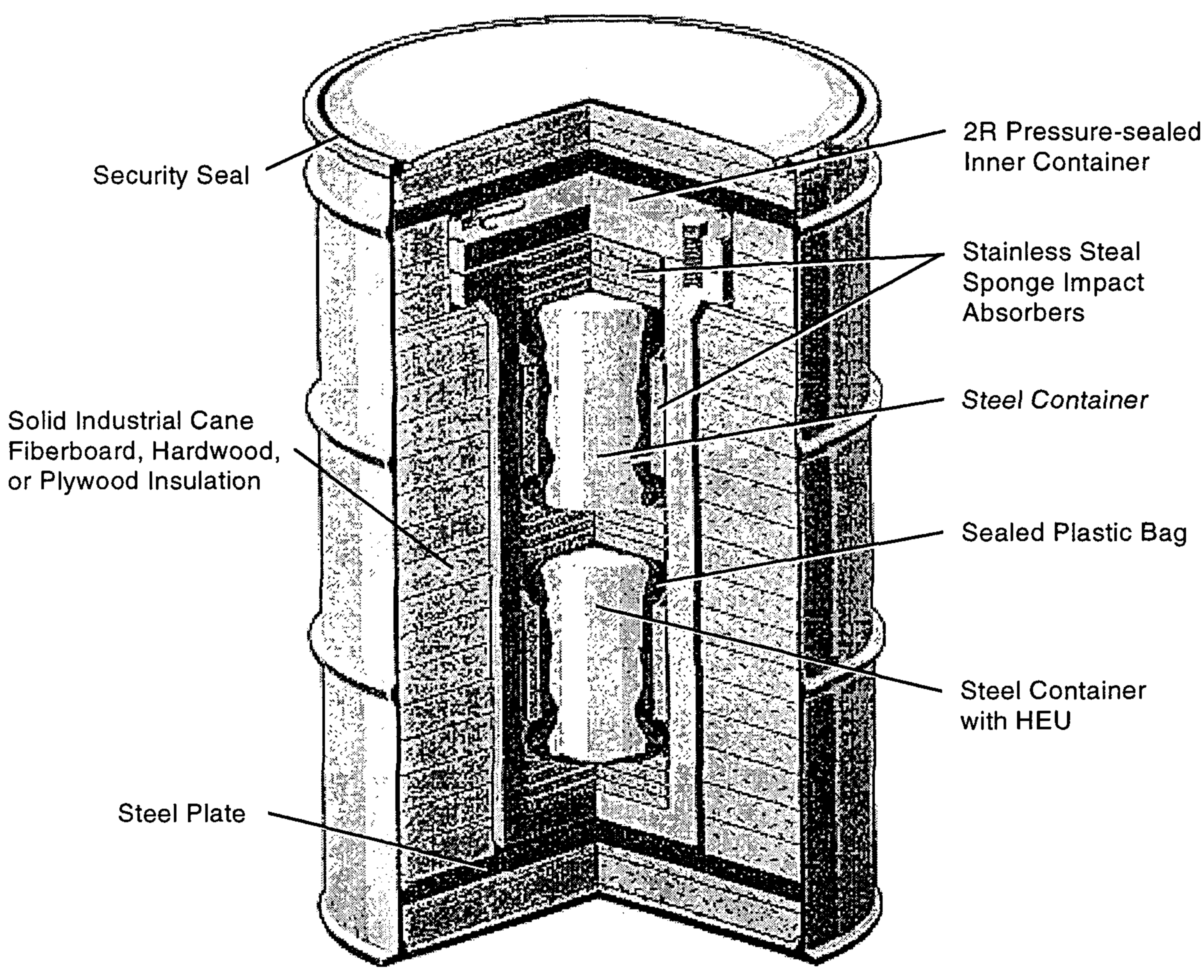

FIGURE F.2.4.4–1.—*55-Gallon (208-Liter) 6M Packaging.*

F.2.4.5 *5320 for Plutonium Oxide and Americium Oxide*

The basic arrangement of the 5320 shipping cask is an upright cylinder with a domed top (see Figure F.2.4.5–1). The weight of the cask is about 327 pounds (149 kilograms), the overall height is 32 inches (81.3 centimeters), and the diameter is 16.75 inches (42.55 centimeters). The cask cavity has a length of 17.5 inches (44.5 centimeters) and a diameter of 1.73 inches (4.39 centimeters). The nested primary and secondary containment vessels are surrounded by a finned aluminum shield tank filled with water-filled polyester. The containers are retained within the central sleeve of the shield tank by a bolt that holds the bottom of the secondary container against the baseplate. Heat from the package contents is conducted to the outer shell of the shield tank by radial aluminum plates that connect the central sleeve to the outer shell. Axial fins on the outer shell dissipate the heat to the environment. An expanded metal screen encloses and protects the fins. The screen also excludes personnel contact during handling operations.

A thermal shield protects the lid, flanges, flange bolts, and seals of the secondary container during thermal accident conditions. A “top hat” style impact limiter protects all of these components during impact accidents.

Secondary containment is provided by the EP–62, which is a cylindrical pressure vessel fabricated from Type 304 stainless steel. Primary containment is provided by the EP–61, which is a Type 316 stainless steel pressure vessel with a threaded plug and cap. The containment seal is provided by seal welding the cap to the body. The EP–61 is certified as a one-time-use container. It is opened by removing the welded cap, thus exposing the threaded plug. Energy absorbers are used to center the primary containment vessel inside the secondary containment vessel.

The americium and plutonium products placed inside handling or product canisters are contained in the primary containment vessel. Possible contents include plutonium oxide and its daughter products or americium oxide in any solid form such as granules, scrap, pellets, or powder. The maximum quantity allowed is 12.6 ounces (357 grams) of plutonium of any isotopic composition or 6.2 ounces (176 grams) of americium. The maximum permissible decay heat is 203 watts (Wangler 1996).

F.2.4.6 *Model 72–B for Remote-Handled Transuranic Waste*

Packaging for remote-handled (RH) TRU waste, which produces penetrating gamma radiation, is now going through the certification process. Compliance with the NRC requirements for Type B packaging has to be demonstrated for the 72–B cask by analysis or by combination of analysis and testing. The 72–B cask is a scaled-down version of the 125–B package, which has been certified by the NRC as a Type B package.

The 72–B (Figure F.2.4.6–1) consists of two concentric stainless steel containment vessels protected by impact limiters at each end. A 2-inch (5-centimeter) lead liner between the inner and outer containment vessels provides shielding against gamma radiation. Neither containment vessel is vented, and each is capable of withstanding an internal pressure of 150 psig. The capacity of the 72–B cask is 8,000 pounds (3,632 kilograms) of payload. The payload consists of RH TRU waste packed in 30- or 55-gallon (114- or 208-liter) drums, which are contained in a carbon steel canister. A shipment of RH TRU waste will involve only one 72–B cask, loaded onto a custom-designed trailer, for truck transport to WIPP (SSEB 1994).

F.2.5 Safe Secure Trailers

DOE maintains and operates a special fleet of trucks and trailers used to transport, in a safe and secure manner, SNM, classified configurations of nuclear weapons systems, and other forms and quantities of strategic materials between U.S. Department of Defense (DoD) sites and DOE production sites, laboratories, and test sites. DOE Albuquerque Operations Office, Transportation Safeguards Division, is responsible for the operation and maintenance of safe secure transport (SST) trailers and supporting vehicles. Because DOE exclusively operates and maintains the SST network, DOE is responsible for evaluating and approving the safe and secure use of the SSTs, both within DOE sites and between sites.

An SST trailer is a modified standard closed semi-trailer that includes necessary cargo tie-down equipment and temperature monitoring, fire alarm, and access denial systems. It is essentially a mobile vault that is highly resistant to unauthorized entry and provides a high degree of cargo protection under accident conditions. The SST trailer is pulled by an armored, penetration-resistant tractor.

SST trailers are accompanied by armed couriers in escort vehicles equipped with communications and electronics systems, radiological monitoring equipment, and other equipment to enhance safety and security. The escort vehicles must meet maintenance standards significantly more stringent than those for similar commercial transport equipment. All vehicles undergo an extensive maintenance check prior to every trip, as well as periodic preventive maintenance inspections. In addition, these vehicles are replaced more frequently than the vehicles used by commercial shippers. Every effort is made to ensure that the convoys do not travel during periods of inclement weather. Should the convoys encounter adverse weather, provisions exist for the convoys to seek secure shelter at previously identified facilities (DOE 1996a).

F.2.6 1-Ton Chlorine Containers

Chlorine is categorized as a Division 2.3 material by DOT. This division is composed of gases that are considered poisonous when inhaled (49 CFR 173.115[c]).

Regulations allow transport of chlorine by rail tank car, tank truck, 1-ton (908-kilogram) container, and gas cylinder. Only 1-ton (908-kilogram) containers and smaller gas cylinders have been used at LANL. (One-ton cylinders are no longer used at LANL as they once were; this type of container is retained for analysis because one cannot preclude their future use.) DOT specification classes for the 1-ton (908-kilogram) container are 106A and 110A. The typical chlorine 1-ton (908-kilogram) container is 81.5 inches (207 centimeters) long with an outside diameter of 30.1 inches (76.5 centimeters). The minimum actual wall thickness is usually 0.4375 inch (1.1 centimeters) (the regulatory minimum is 0.406 inch [1.0 centimeter]). The ends of the cylinder are recessed to protect valves, which are also covered by a protective bonnet. Fusible plugs in both ends are designed to open if the temperature exceeds 155°F (68°C). The capacity is 2,000 pounds (908 kilograms) of chlorine.

F.2.7 Liquid Propane Cargo Tank

Liquid propane is transported by rail tank car, tank truck, and cargo tank. The cargo tank is used primarily for local deliveries and will transport up to 2,500 gallons (9,463 liters) of liquid propane. Deliveries to LANL are by cargo truck and are usually in 2,000-gallon (7,570-liter) increments. The cargo tank is 15 feet (4.6 meters) long and 6 feet (1.8 meters) in diameter. Its walls are 0.394 inch (1.0 centimeter) thick. The tank is permanently mounted on a 14-ton (12,712-kilogram) truck body. Valves and piping are located at the rear of the truck. The tank pressure of 250 psi keeps the propane in a liquid state.

F.2.8 Explosives

Explosives are classified as Divisions 1.1 through 1.6 materials:

- *Division 1.1*—Materials that present a mass explosion hazard.
- *Division 1.2*—Materials that present a projection hazard, but not a mass explosion hazard.
- *Division 1.3*—Materials that present a fire hazard and a minor blast or project hazard (or both), but not a mass explosion hazard.
- *Division 1.4*—Materials that present minor explosion hazard.
- *Division 1.5*—Materials that present a mass explosion hazard, but that are also considered insensitive in terms of initiation of explosion.
- *Division 1.6*—Materials that are considered extremely insensitive and do not present a mass explosion hazard.

In the past, shipments to and from LANL have included materials in Divisions 1.1, 1.2, and 1.4.

Typical packages transported to LANL contain 50 pounds (22.7 kilograms) of explosives in a No. 4 fiber carton with a 4-millimeter-thick polyethylene liner. Up to 36 cartons are stacked on a wooden pallet and restrained by stretch netting. Up to 38,800 pounds (17,615 kilograms) of explosives may be transported to LANL in a tractor trailer.

F.3 RISK MEASURES

In this section, basic risk concepts are presented, key features of the transportation quantitative risk analysis are discussed, and the four risk measures used in the transportation risk analysis are described. The transportation risk analysis methodology is illustrated in Figure F.3–1.

F.3.1 Risk Concepts

The terms hazard and risk are synonymous in everyday usage but are quite different in technical language. A hazard is the inherent characteristic of a material, condition, or activity that has the potential to cause harm to people, property, or the environment. A tank pressurized with air has the potential to cause harm to people from flying fragments that would result should the tank fail. An unpressurized tank filled with HAZMAT has the potential to cause harm because of the hazardous nature and quantity of material that could be released.

Risk is the combination of the likelihood and the consequence of a specified hazard becoming uncontrolled. The specified uncontrolled hazard is the result of an accident scenario. A scenario usually consists of a sequence of events. The events are sometimes shown graphically in an event tree (section F.4.5). Likelihood can be expressed as either a frequency or a probability. Frequency is the rate at which events occur (e.g., events per year, accidents per mile). The frequency component of risk often consists of the initiating event frequency multiplied by several conditional probability terms. A probability is a number between 0 and 1 that expresses a degree of belief concerning the possible occurrence of an event. In this appendix, the term probability usually reflects a conditional probability. A conditional probability is a probability for an event that has been preceded by one or more specified events. Consequence is the direct effect, usually undesirable, of the accident scenario. Consequences usually are measured in health effects but may be expressed as cost of property loss or the amount of HAZMAT released.

Risk often is defined as frequency times consequence. However, important information

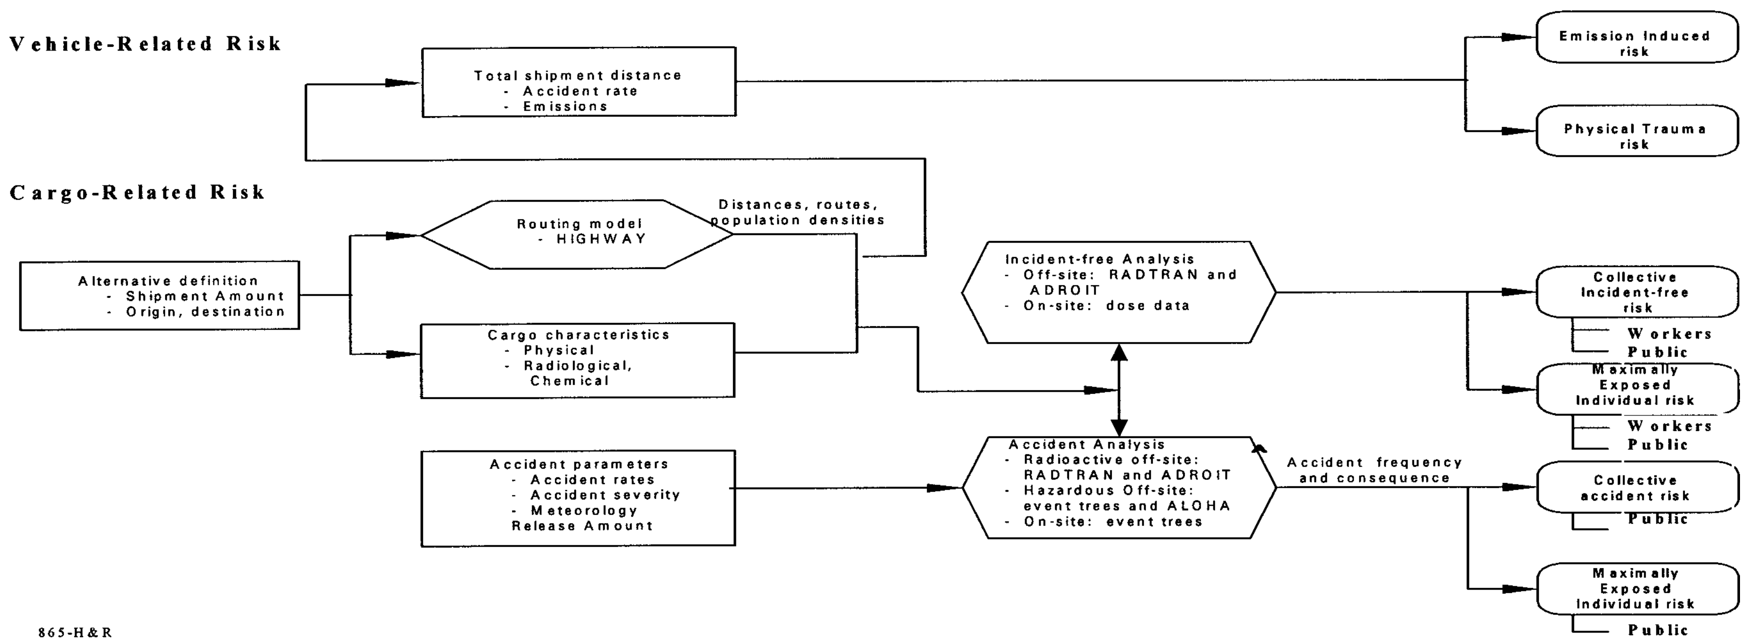

FIGURE F.3–1.—*Transportation Risk Analysis Methodology.*

may be lost when risk is expressed as the product of frequency and consequence. When frequency (or probability) is multiplied by consequence, an accident that is expected to cause one fatality and occur 10 times a year has the same mathematical risk as an accident that is expected to cause 1,000 fatalities and occur once every 100 years. Impact analysis results reported as risk values in sections F.6 and F.7 are the products of frequency and consequence to be consistent with the computer codes used to generate the results.

A quantitative risk analysis incorporates numerical estimates of the frequencies and the consequences in a sophisticated but approximate manner. In practice, few decisions require quantification of both frequency and consequence at equal levels of sophistication. Although risk assessment and risk analysis usually are used interchangeably, risk analysis is defined in the SWEIS as the computation of risks, whereas risk assessment is defined as the determination of risk acceptability. Taking action to mitigate risks is part of risk management.

F.3.2 Transportation Risk Key Parameters

A mathematical formulation specifically for transportation risk will illustrate the important parameters used in this appendix. The risk, R_i, for accident scenario *i* is a function of the scenario frequency, F_i, and the scenario consequence, C_i (Equation F-1).

$$R_i = f(F_i , C_i) \qquad \text{(F–1)}$$

The usual procedure for a quantitative transportation risk analysis is to divide the transport route into segments (also called links), along which the important parameters can be reasonably approximated by a single average value. A detailed expression for risk can then be formulated as follows (Equation F-2) (Rhyne 1994a):

$$R_i = f(F_{1a} \times M_a \times P_{2ab} \times P_{3abc} \times P_{4ad} \times P_{5ae} , N_{ad} \times A_{abc} \times X_{ace}) \qquad \text{(F–2)}$$

Where: F_{1a} = frequency of an accident per mile in transport link *a*, based, in the case of truck transport, primarily on highway type and conditions, vehicle type, and traffic conditions;

M_a = number of miles, or miles per year, in link *a*;

P_{2ab} = probability that the accident in link *a* results in accident forces of type *b* (e.g., mechanical or thermal forces);

P_{3abc} = probability that the magnitude of accident force type *b* in link *a* exceeds the container's capability to resist the force and causes release class *c* to occur;

P_{4ad} = probability that population distribution class *d* occurs in link *a*;

P_{5ae} = probability that meteorological condition *e* occurs in link *a*;

N_{ad} = number of persons per unit area in population class *d* in link *a*;

A_{abc} = release amount for release class *c*, given that force type *b* occurs in link *a*; and

X_{ace} = area that experiences the specified health effects from a unit release of the hazardous material for meteorological condition *e* for release class *c*.

The overall risk is obtained by summing all scenarios for each link or for the entire route (Equation F-3).

$$R = \sum Ri \qquad \text{(F–3)}$$

The risk expression (Equation F-2) shows that risk is directly proportional to nine parameters, the quantification of which is described in section F.4 of this appendix. The key parameters affecting the frequency term are accident rate (subsection F.4.2), mileage (subsection F.4.3), and accident severity and package release probabilities (subsection F.4.4.2). The key parameters affecting the consequence term are population density (subsection F.4.3), release amount (subsection F.4.4.3), and meteorological conditions.

Two of the parameters in Equation F-2 (specific population density and specific meteorology) are not mentioned in section F.4. These conditional probabilities are conservatively valued as 1.0 in this transportation risk analysis.

F.3.3 Truck-Related Risk Measures

Trucks carry cargo as varied as radioactive and HAZMAT, steel girders, and vegetables. Truck traffic on public highways presents two types of health risks independent of the nature of the cargo: the health effect of air pollutants, primarily the diesel fuel combustion products; and the injuries and fatalities caused by truck accidents.

F.3.3.1 *Truck Emissions*

Truck traffic produces air pollution from the diesel engine exhaust, fugitive dust generated by the vehicle wake on the highway surface dust, and particulates from tire wear on the paved surface. The primary health effect of diesel fuel combustion is caused by sulfur oxides and particulates, although nitrogen oxides and hydrocarbons are also produced. The health effect of these pollutants is increased sickness (morbidity) and death, generally occurring after a latency period of several years. The health effect has been evaluated by Rao, et al. (1982) as 1.0 x 10^{-7} fatalities per truck kilometer in urban areas. No analysis was made for morbidity because no data were available. The result is limited to urban areas because the available air pollution mortality data were limited to metropolitan population subgroups.

To evaluate this risk measure, the number of truck miles in urban areas (evaluated as described in subsection F.4.3) associated with RAM and HAZMAT shipments is multiplied by the health effect conversion factor described in the previous paragraph. Given truck travel in an urban area, the frequency of this consequence is 1; i.e., it is certain to occur.

F.3.3.2 *Truck Accident Injuries and Fatalities*
